Chapter 2

GMS

2.1 Case Study: the GMS model

The Gierer-Meinhardt system [1], with saturation, is given by the following pair of nonlinear pdes; a system in a family sometimes referred to as reaction-diffusion equations:

$$\begin{aligned}u_t &= D_u \Delta u + a(u, v) = D_u \Delta u - u + \frac{u^2}{v(1 + ku^2)} \\ \tau v_t &= D_v \Delta v + b(u, v) = D_v \Delta v - v + u^2,\end{aligned}\tag{2.1}$$

with $D_u = \varepsilon^2, D_v = D/\varepsilon$, plus homogeneous Neumann boundary conditions on $x \in [0, 1]$. We consider the limit where $\varepsilon \ll 1$, and regard all the other constants as being $O(1)$.

2.1.1 Construction of the solution in the near-shadow limit

For the near-shadow limit, $D = \mathcal{D}/\varepsilon$, we want to construct a K -stripe stationary solution on $x \in [0, 1]$, with $L = 1/K$ the period of the solution, and l the length of each individual mesa, as shown in figure (2.1). The stationary equation we want to

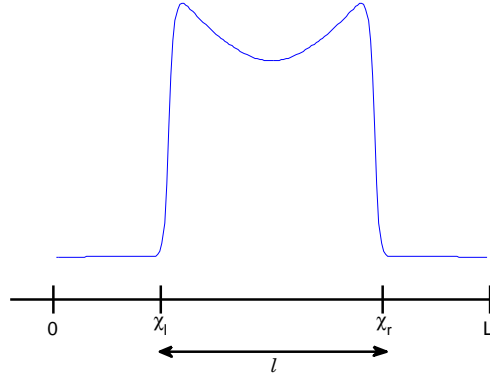

Figure 2.1: A typical mesa profile in the stationary solution $v(x)$. The left and right edges of the mesa are labelled as χ_l and χ_r respectively; and the length of the mesa section is l .

solve is

$$\begin{aligned} 0 &= \varepsilon^2 u_{xx} - u + \frac{u^2}{v(1+ku^2)}, & u_x(0) &= u_x(L) = 0, \\ 0 &= \frac{\mathcal{D}}{\varepsilon} v_{xx} - v + u^2, & v_x(0) &= v_x(L) = 0. \end{aligned} \quad (2.2)$$

did not define $g(u, v) = \frac{u^2}{v(1+ku^2)}$, as it's only used much further down the road

To first order, we have in the v equation that $v_{xx} = 0$. Applying the Neumann condition, we have then that $v \sim \mathcal{V}$, and the value of the constant can be estimated by integrating over the whole domain,

$$\mathcal{V} = \frac{1}{L} \int_0^L u^2 dx. \quad (2.3)$$

In the inner region near the left boundary of the mesa we have that $v = \mathcal{V}$, and we do a change of variables for $u = \mathcal{V}w$ and $y = \varepsilon^{-1}(x - \chi_l)$. The resulting equation is

$$w_{yy} + f(w) = 0, \quad -\infty < y < \infty, \quad f(w) = -w + \frac{w^2}{1+bw^2}, \quad (2.4)$$

with $b = k\mathcal{V}^2$. Now, we are looking for a heteroclinic connection in u as the transition mechanism that generates the mesa, one for the each side of the mesa. For a heteroclinic connection to exist in (2.4), it has to satisfy the Maxwell line condition [3].

The function $f(w) = 0$ has zeros at $w = 0$ and $w_{\pm} = \frac{1 \pm \sqrt{1-4b}}{2}$, with distinct real values for w_{\pm} existing in the range $0 \leq b < 1/4$. The profile of the curve in that range can be seen in figure (2.2). The Maxwell line condition states that a heteroclinic connection will exist for the value $b = b_0$ such that $\int_0^{w_+} f(w) dw = 0$.

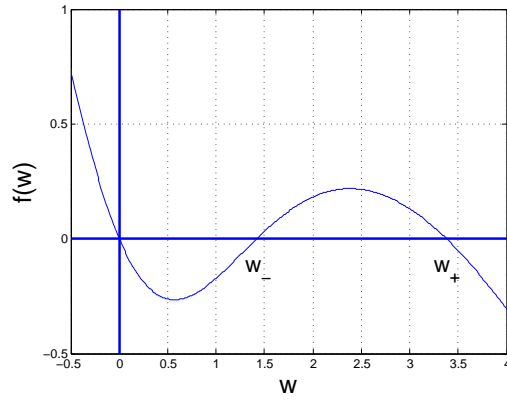

Figure 2.2: A plot of the function $f(w)$ given in (2.4).

Integrating $f(w)$ we get

$$\begin{aligned} \int_0^{w_+} f(w)dw &= \left(-\frac{w^2}{2} + \frac{w}{b} - \frac{1}{b^{3/2}} \arctan(b^{1/2}w) \right) \Big|_0^{w_+}, \\ &= -\frac{w_+^2}{2} + \frac{w_+}{b_0} - \frac{1}{b_0^{3/2}} \arctan(b_0^{1/2}w_+), \end{aligned}$$

and since we have that $b_0 = \frac{w_+ - 1}{w_+^2}$, the Maxwell line condition will be satisfied if

$$b_0 = \frac{w_+ - 1}{w_+^2}, \quad \sqrt{w_+ - 1}(w_+ + 1) = 2w_+ \arctan(\sqrt{w_+ - 1}). \quad (2.5)$$

This can be solved numerically to obtain the critical values $b_0 = 0.211376$, and $w_+ = 3.295209$. (??? do a plot of numerical vs asymptotic approximation)

For use later in section (2.1.2), we need to compute

$$\beta = \int_{-\infty}^{\infty} w'^2 dy$$

We multiply (2.4) by w' to get

$$\frac{d}{dy} \left(\frac{w'^2}{2} \right) = \frac{d}{dy} \mathcal{F}(w) \quad \rightarrow \quad w'^2 = 2\mathcal{F},$$

with $\mathcal{F} = \int_0^w f(s)ds$. We then get

$$\beta = \int_{-\infty}^{\infty} w'^2 dy = \int_0^{w_+} w'^2 \frac{1}{w'} dw = \int_0^{w_+} \sqrt{2\mathcal{F}(w)} dw. \quad (2.6)$$

This can be numerically calculated using the previously computed value for w_+ , to get $\beta \sim 1.49882$.

Linearizing around $w = 0$ for $y \rightarrow -\infty$, and for $w = w_+$ for $y \rightarrow \infty$, we get that for $b = b_0$ we have a heteroclinic solution

$$\begin{aligned} w'' + f(w) &= 0, & -\infty < y < \infty, & \quad f(w) = -w + \frac{w^2}{1 + b_0 w^2}, \\ w &\sim d_- e^y, & \text{as } y &\rightarrow -\infty, \\ w &\sim w_+ - d_+ e^{-w_+ y}, & \text{as } y &\rightarrow \infty, \end{aligned}$$

for $v_+ = \sqrt{1-2/w_+}$. By translation we take $w(0) = w_+/2$, in order to have uniqueness.

A full mesa solution will consist of two back-to-back heteroclinic curves, and can be constructed as

$$u \sim \mathcal{V}[w_l + w_r - w_+], \quad \text{with } w_l \sim w \left(\frac{x - \chi_l}{\varepsilon} \right), \quad w_r \sim w \left(\frac{\chi_r - x}{\varepsilon} \right).$$

Integrating (2.3), we get that to first order $\mathcal{V} \sim \frac{1}{L} \mathcal{V}^2 w_+^2 l$, with $l = \chi_r - \chi_l$ the width of the mesa. We then have

$$\mathcal{V} w_+^2 \sim \frac{L}{l} + O(\varepsilon), \quad l \sim \frac{L\sqrt{k}}{\sqrt{b_0} w_+^2} < L,$$

therefore a necessary condition for a K -stripe solution to exist is that

$$\frac{\sqrt{k}}{\sqrt{b_0} w_+^2} < 1.$$

To refine the solution, it is necessary to further expand $u(x)$ and $v(x)$. In the outer region we expand u and v as

$$v \sim \mathcal{V} + \varepsilon v_1 + \varepsilon^2 h_2 + \dots.$$

Since outside of the mesa u is exponentially small, and in the plateau region $u \sim \mathcal{V} w_+ + O(\varepsilon)$, by substituting into (2.2), we get that

$$\mathcal{D}v_{1,xx} = \begin{cases} \mathcal{V} & \text{for } 0 < x < \chi_l \\ \mathcal{V}(1 - \mathcal{V} w_+^2) = \mathcal{V}(1 - L/l) & \text{for } \chi_l < x < \chi_r \\ \mathcal{V} & \text{for } \chi_r < x < L \end{cases} \quad (2.7)$$

with $v_{1,x}(0) = v_{1,x}(L) = 0$. In order to find the conditions on v_1 at the transition layers χ_l and χ_r , we expand u as $u \sim \mathcal{V} w_+ + \varepsilon \mathcal{U}_1 + \dots$ on $\chi_l < x < \chi_r$.

Substituting into (2.2), we get that

$$-\mathcal{U}_1 + g_u(\mathcal{V}w_+, \mathcal{V})\mathcal{U}_1 + g_v(\mathcal{V}w_+, \mathcal{V})v_1 = 0.$$

Since $1 + b_0w_+^2 = w_+$, the linearization terms simplify to

$$\begin{aligned} g_u(\mathcal{V}w_+, \mathcal{V}) &= \frac{2w_+}{(1 + b_0w_+^2)^2} = \frac{2}{w_+}, \\ g_v(\mathcal{V}w_+, \mathcal{V}) &= \frac{-w_+^2}{1 + b_0w_+^2} = -w_+, \end{aligned} \tag{2.8}$$

and this yields

$$-\mathcal{U}_1 + \frac{2}{w_+}\mathcal{U}_1 - w_+v_1 = 0, \quad \Rightarrow \quad \mathcal{U}_1 = \frac{w_+^2}{2 - w_+}v_1.$$

We now expand u and v near the $x = \chi_l$ ($y = \varepsilon^{-1}(x - \chi_l)$) as

$$u = u_0 + \varepsilon u_1 + \varepsilon^2 u_2 + \cdots, \quad v = \mathcal{V} + \varepsilon \mathcal{V}_1 + \varepsilon^2 \mathcal{V}_2 + \cdots,$$

with $u_0 = \mathcal{V}w_+$. Substituting into (2.2), the $O(\varepsilon)$ system is

$$\begin{aligned} \mathcal{L}u_1 &\equiv u_1'' - u_1 + g_u(u_0, \mathcal{V})u_1 = -g_v(u_0, \mathcal{V})\mathcal{V}_1 \\ \mathcal{V}_1'' &= 0. \end{aligned} \tag{2.9}$$

For \mathcal{V}_1 we get that $\mathcal{V}_1 = \mathcal{V}_{10} + \mathcal{V}_{11}y$. We have that $\mathcal{L}a'_0 = 0$.

The solvability condition on (2.9) is then that

$$\int_{-\infty}^{\infty} g_v(u_0, \mathcal{V})\mathcal{V}_1 u_0' dy = \int_{-\infty}^{\infty} \frac{w^2}{1 + bw^2} w' \mathcal{V}_1 dy = 0. \tag{2.10}$$

Substituting in $\mathcal{V}_1 = \mathcal{V}_{10} + \mathcal{V}_{11}y$, the condition from (2.10) implies that

$$\mathcal{V}_{10} \int_{-\infty}^{\infty} \frac{w^2 w'}{1 + bw^2} dy + \mathcal{V}_{11} \int_{-\infty}^{\infty} \frac{w^2 w' y}{1 + bw^2} dy = 0.$$

Since $\mathcal{V}_1 = O(\varepsilon)$, \mathcal{V}_{11} has to be zero, as otherwise for $|y| \gg 1$ we would have $\mathcal{V}_1 = O(1)$. Consequently, \mathcal{V}_{10} also has to be zero, and the conclusion is that $\mathcal{V}_1 = 0$. We have then that $\mathcal{L}u_1 = 0$, and therefore we also have $u_1 = 0$

This result yields that

$$v_1(\chi_l) = v_1(\chi_r) = 0,$$

and now we have enough conditions to solve uniquely for v_1 .

Using the fact that $\chi_r - \chi_l = l$, and that $\mathcal{V}w_+^2 = L/l$, the full solution to (2.7) is

$$v_1 = \begin{cases} \frac{\mathcal{V}}{2\mathcal{D}}(x^2 - \chi_l^2) & \text{for } 0 < x < \chi_l \\ \frac{\mathcal{V}(l-L)}{2\mathcal{D}l}[(x - \chi_l)^2 - l(x - \chi_l)] & \text{for } \chi_l < x < \chi_r \\ \frac{\mathcal{V}}{2\mathcal{D}}[(L - x)^2 - (L - \chi_r)^2] & \text{for } \chi_r < x < L \end{cases}$$

It is possible now to calculate $v_{1,x}$ close to the transition layers. We have

$$\begin{aligned} v_{1,x}(\chi_l^-) &= \frac{\mathcal{V}\chi_l}{\mathcal{D}}, & v_{1,x}(\chi_l^+) &= \frac{\mathcal{V}(L-l)}{2\mathcal{D}}, \\ v_{1,x}(\chi_r^-) &= -\frac{\mathcal{V}(L-l)}{2\mathcal{D}}, & v_{1,x}(\chi_r^+) &= -\frac{\mathcal{V}(L-\chi_r)}{\mathcal{D}}, \end{aligned} \quad (2.11)$$

This suggests that there is a term to next order, as $\mathcal{V}_2 \sim v_{1,x}(\chi_l)$. Expanding to next order in the inner region, as $u = u_0 + \varepsilon^2 u_2$ and $v = \mathcal{V} + \varepsilon^2 \mathcal{V}_2$, and defining $g_0(w) = \frac{w^2}{1+b_0 w^2}$, we have the system

$$\begin{aligned} \mathcal{L}u_2 &= u_2'' - u_2 + g_0'(w)u_2 = g_0(w)\mathcal{V}_2, \\ \mathcal{V}_2'' &= 0. \end{aligned}$$

We have then that $\mathcal{V}_2 = \mathcal{V}_{20} + y\mathcal{V}_{21}$.

We can derive a solvability condition from $\mathcal{L}u_2 = g_0(w)\mathcal{V}_2$, since $\mathcal{L}w' = 0$. We get

$$\int_{-\infty}^{\infty} \mathcal{V}_2 g_0(w) w' dy = \int_{-\infty}^{\infty} (\mathcal{V}_{20} + y\mathcal{V}_{21}) g_0(w) w' dy = 0,$$

We can now match the inner solution to the outer solution evaluated at the interface, to determine \mathcal{V}_{20} and \mathcal{V}_{21} . We get that

$$\mathcal{V} + \varepsilon^2(\mathcal{V}_{20} + y\mathcal{V}_{21}) + \dots = \mathcal{V} + \varepsilon v_1(\chi_l) + \varepsilon v_{1,x}(\chi_l^-)(x - \chi_l) + \varepsilon^2 v_2(\chi_l) + \dots$$

From this we can conclude that $\mathcal{V}_{21} = v_{1,x}(\chi_l^-)$, and that $\mathcal{V}_{20} = v_2(\chi_l)$. This last value, for both the inner and outer solutions, can be calculated from the solvability condition given that we now know \mathcal{V}_{21} .

Furthermore, repeating the matching procedure with $x \rightarrow \chi_l^+$ yields the same value, as the outer solution has no ambiguity. From this we get that $v_{1,x}(\chi_l^+) = v_{1,x}(\chi_l^-)$. Repeating the procedure yet again at the right boundary χ_r , we get the same result, i.e., $v_{1,x}(\chi_r^+) = v_{1,x}(\chi_r^-)$. Since we already knew from (2.11) that $v_{1,x}(\chi_l^+) = -v_{1,x}(\chi_r^-)$, we can solve for χ_l and χ_r to get that the position of the boundaries of the mesa on $[0, L]$ are

$$\chi_l = \frac{L-l}{2}, \quad \chi_r = \frac{L+l}{2},$$

with l the length of the plateau. A corollary from this result is that stationary mesa solutions have to be centred.

We can find a second solvability condition that will be of use later on. Differentiating with respect to y , we have

$$\mathcal{L}u_2' = -g_0''(w)u_2w' + g_0(w)\mathcal{V}_2' + g_0'(w)\mathcal{V}_2w',$$

and using the fact that $\mathcal{L}w' = 0$, the solvability condition we get is

$$\begin{aligned} -\mathcal{V}_{21} \int_{-\infty}^{\infty} g_0(w) w' dy &= \int_{-\infty}^{\infty} (g_0'(w) \mathcal{V}_2 - g_0''(w) u_2) w'^2 dy, \\ v_{1,x}(\chi_r) \int_{-\infty}^{\infty} g_0(w) w' dy &= \int_{-\infty}^{\infty} (g_0'(w) \mathcal{V}_2 - g_0''(w) u_2) w'^2 dy, \end{aligned} \quad (2.12)$$

since $\mathcal{V}_2' = \mathcal{V}_{21} = -v_{1,x}(\chi_r)$.

2.1.2 Stability in the near-shadow limit to perturbations in the y direction

We assume that the solutions exist in a rectangular domain $[0, 1] \times [0, d_0]$, with Neumann boundary conditions on all sides. We introduce a perturbation on the equilibrium solution (u_e, v_e) of the form

$$u = u_e + e^{\lambda t_{\text{tiny}}} \phi(x), \quad v = v_e + e^{\lambda t_{\text{tiny}}} \psi(x); \quad m = \frac{k\pi}{d_0}, k = 1, 2, \dots,$$

with $|\phi(x)| \ll 1$, and $|\psi(x)| \ll 1$.

Substituting into (2.1), we get the following eigenvalue problem

$$\bar{\lambda} \phi = \mathcal{L}_\varepsilon \phi + g_v(u_e, v_e) \psi = \varepsilon^2 \phi_{xx} - \phi + g_u(u_e, v_e) \phi + g_v(u_e, v_e) \psi, \quad (2.13a)$$

$$\frac{\varepsilon}{\mathcal{D}}(1 + \tau \lambda) \psi = \psi_{xx} - m^2 \psi + \frac{2\varepsilon}{\mathcal{D}} u_e \phi, \quad (2.13b)$$

with $\bar{\lambda} = \lambda + \varepsilon^2 m^2$, and Neumann conditions $\phi_x(0) = \phi_x(1) = \psi_x(0) = \psi_x(1) = 0$.

As shown in (2.8), in the plateau region we have that $g_u(u_e, v_e) = 2/w_+$, and $g_v(u_e, v_e) = -w_+$. Substituting into (2.13a), we have that, to first order, when $\bar{\lambda} \ll 1$ (???), the asymptotic form of ϕ on the plateau region is

$$\phi = \mu \psi, \quad \text{with } \mu \equiv \frac{w_+^2}{2 - w_+}, \quad \chi_l < x < \chi_r.$$

Outside of the plateau region ϕ is asymptotically small, therefore near the transition layers located at χ_l, χ_r , ϕ is proportional to the derivative w' of the heteroclinic connection. We have then the following asymptotic form for ϕ

$$\phi \sim \begin{cases} c_{li}(w'(\varepsilon^{-1}(x - \chi_{li})) + O(\varepsilon)) & \text{for } x \sim \chi_{li} \\ c_{ri}(w'(\varepsilon^{-1}(\chi_{ri} - x)) + O(\varepsilon)) & \text{for } x \sim \chi_{ri} \\ \phi_i = \mu \psi & \text{for } x \in (\chi_{li}, \chi_{ri}), \quad i = 1, \dots, K, \end{cases}$$

with the constants c_{li}, c_{ri} to be found.

Since ϕ is localized near the transition layers, we can estimate it in the sense of distributions, approximating u_e as $u_e \sim \mathcal{V} w$

$$\begin{aligned} \frac{2\varepsilon u_e \phi}{\mathcal{D}} &\sim \frac{2\varepsilon^2 \mathcal{V} c_l}{\mathcal{D}} \int_{-\infty}^{\infty} w_l w'_l dy \delta(x - x_l) + \dots \\ &\quad + \frac{2\varepsilon^2 \mathcal{V} c_r}{\mathcal{D}} \int_{-\infty}^{\infty} w_r w'_r dy \delta(x - x_r) + \frac{2\varepsilon \mathcal{V}}{\mathcal{D}} w_+ \mu \psi H_{[\chi_l, \chi_r]}, \end{aligned}$$

with $H_{[\chi_l, \chi_r]} = 1$ on $x \in (\chi_l, \chi_r)$, and zero elsewhere.

This then yields

$$\frac{2\varepsilon u_e \phi}{\mathcal{D}} \sim \frac{\varepsilon^2 \mathcal{V} c_l w_+^2}{\mathcal{D}} \delta(x - x_l) + \frac{\varepsilon^2 \mathcal{V} c_r w_+^2}{\mathcal{D}} \delta(x - x_r) + \frac{2\varepsilon \mathcal{V} w_+ \mu \psi H}{\mathcal{D}}$$

Substituting into (2.13b), we get that ψ satisfies

$$\psi_{xx} - \theta^2 \psi = -\frac{\varepsilon^2 \mathcal{V} w_+^2}{\mathcal{D}} \left[\sum_i (c_{li} \delta(x - \chi_{li}) + c_{ri} \delta(x - \chi_{ri})) \right], \quad (2.14)$$

with θ the piecewise constant function

$$\theta = \begin{cases} \theta_- \equiv \left(m^2 + \frac{\varepsilon(1+\tau\lambda)}{\mathcal{D}} \right)^{1/2}, & \text{for } x \notin \cup_{i=1}^K [\chi_{li}, \chi_{ri}] \\ \theta_+ \equiv \left(m^2 + \frac{\varepsilon(1+\tau\lambda)}{\mathcal{D}} \left(1 + \frac{2w_+}{l(w_+-2)} \right) \right)^{1/2}, & \text{for } x \in \cup_{i=1}^K [\chi_{li}, \chi_{ri}] \end{cases} \quad (2.15)$$

Since w' is localized, we can define $w'_{li} = w'(x - \chi_{li})$ and $w'_{ri} = w'(\chi_{ri} - x)$, and multiply it into (2.13a), to obtain the matrix eigenvalue problem

$$c_{li}(w'_{li}, \mathcal{L}_\varepsilon w'_{li}) + (w'_{li}, g_v(u_e, v_e)\psi) = c_{li}\bar{\lambda}(w'_{li}, w'_{li}), \quad (2.16)$$

and similarly

$$c_{ri}(w'_{ri}, \mathcal{L}_\varepsilon w'_{ri}) + (w'_{ri}, g_v(u_e, v_e)\psi) = c_{ri}\bar{\lambda}(w'_{ri}, w'_{ri}), \quad (2.17)$$

where $(f, g) = \int_0^1 fg dx$.

The second term in (2.16) and (2.17) can be readily estimated, using the fact that $w'' - w = g_0(w)$, and that $g_v = -g_0$, as

$$\begin{aligned} (w'_{li}, g_v(u_e, v_e)\psi) &= \int_0^1 w'_{li} \psi g_v(u_e, v_e) dx = -\varepsilon \psi(\chi_l) \int_{-\infty}^{\infty} w' g_0(w) dy \\ &= -\varepsilon \psi(\chi_l) \int_{-\infty}^{\infty} w'(w'' - w) dy = -\varepsilon \psi(\chi_l) \frac{w_+^2}{2}, \end{aligned}$$

and similarly,

$$(w'_{ri}, g_h(u_e, v_e)\psi) = -\varepsilon \psi(\chi_r) \frac{w_+^2}{2}.$$

The third term can be estimated straight from the definition of β in (2.6). We get

$$(w'_{li}, w'_{li}) \sim \varepsilon \int_{-\infty}^{\infty} (w')^2 dy = \varepsilon \beta.$$

The first term can be estimated using some of the results previously obtained. We have that

$$\mathcal{L}_\varepsilon w'_l = (w'_l)'' - w'_l + g_u(u_e, v_e)w'_l.$$

We can approximate $g_u(u_e, v_e)$ as

$$g_u(u_e, v_e) \sim g_u(w\mathcal{V}, \mathcal{V}) + \varepsilon^2(g_{uu}(w\mathcal{V}, \mathcal{V}) + g_{uv}(w\mathcal{V}, \mathcal{V})) + \dots.$$

The derivatives can be related to $g_0(w) = \frac{w^2}{1+b_0w^2}$ in the following way:

$$\begin{aligned} g_u(u, v) &= \frac{2u}{v(1+ku^2)^2} \sim \frac{2w}{(1+b_0w^2)^2} = g'_0(w), \\ g_{uu}(u, v) &= \frac{1}{v} \frac{2-6ku^2}{(1+ku^2)^3} \sim \frac{1}{\mathcal{V}} \frac{2-6b_0w^2}{(1+b_0w^2)^3} = \frac{1}{\mathcal{V}} g''_0(w), \\ g_{uv}(u, v) &= -\frac{2u}{v^2(1+ku^2)^2} \sim -\frac{2w}{\mathcal{V}(1+b_0w^2)^2} = -\frac{1}{\mathcal{V}} g'_0(w). \end{aligned}$$

Substituting them in, we get

$$\begin{aligned} g_u(u_e, v_e) &\sim g'_0(w) + \frac{\varepsilon^2}{\mathcal{V}}(g''_0(w)u_2 - g'_0(w)\mathcal{V}_2) + \dots, \\ \mathcal{L}_\varepsilon w'_{li} &\sim \frac{\varepsilon^2}{\mathcal{V}}(g''_0(w_{li})u_2 - g'_0(w_{li})\mathcal{V}_2)w'_{li}. \end{aligned}$$

We then get for the first term

$$\begin{aligned} (w'_{li}, \mathcal{L}_\varepsilon w'_{li}) &\sim \frac{\varepsilon^2}{\mathcal{V}} \int_0^1 (g''_0(w_{li})u_2 - g'_0(w_{li})\mathcal{V}_2) w'^2_{li} dx \\ &= \frac{\varepsilon^3}{\mathcal{V}} \int_{-\infty}^{\infty} (g''_0(w_{li})u_2 - g'_0(w_{li})\mathcal{V}_2) w'^2_{li} dy \end{aligned}$$

Using the solvability condition in (2.12),

$$\mathcal{V}'_2 \int_{-\infty}^{\infty} g_0(w) w' dy = \int_{-\infty}^{\infty} (g'_0(w)\mathcal{V}_2 - g''_0(w)u_2) w'^2 dy,$$

we get

$$\begin{aligned} (w'_{li}, \mathcal{L}_\varepsilon w'_{li}) &\sim \frac{\varepsilon^3}{\mathcal{V}} \mathcal{V}'_2 \int_{-\infty}^{\infty} g_0(w) w' dy = \frac{\varepsilon^3}{\mathcal{V}} \mathcal{V}'_2 \int_{-\infty}^{\infty} (w - w'') w' dy \\ &= \frac{\varepsilon^3 \mathcal{V}'_2}{2\mathcal{V}} w_+^2 = \frac{\varepsilon^3 v_{1x}(\chi_{li}) w_+^2}{2\mathcal{V}} \end{aligned}$$

Similarly, on the other side of the plateau the process is identical, except for a sign change in the slope,

$$(w'_{ri}, \mathcal{L}_\varepsilon w'_{ri}) \sim -\frac{\varepsilon^3 v_{1x}(\chi_{ri}) w_+^2}{2\mathcal{V}}$$

Putting everything together results in the following $2K \times 2K$ system

$$\begin{aligned} \varepsilon \bar{\lambda} c_{li} \beta &\sim \frac{\varepsilon^3}{2\mathcal{V}} c_{li} v_{1x}(\chi_{li}) w_+^2 - \frac{\varepsilon}{2} \psi(\chi_{li}) w_+^2, \\ \varepsilon \bar{\lambda} c_{ri} \beta &\sim -\frac{\varepsilon^3}{2\mathcal{V}} c_{ri} v_{1x}(\chi_{li}) w_+^2 - \frac{\varepsilon}{2} \psi(\chi_{ri}) w_+^2, \end{aligned}$$

and since from (2.11) we know that

$$v_{1x}(\chi_{li}) = \frac{\mathcal{V}(L-l)}{2\mathcal{D}},$$

the above system can be simplified to

$$\begin{aligned} \bar{\lambda} \beta c_{li} &\sim \varepsilon^2 \frac{(L-l)w_+^2}{4\mathcal{D}} c_{li} - \frac{w_+^2}{2} \psi(\chi_{li}), \\ \bar{\lambda} \beta c_{ri} &\sim -\varepsilon^2 \frac{(L-l)w_+^2}{4\mathcal{D}} c_{ri} - \frac{w_+^2}{2} \psi(\chi_{ri}). \end{aligned} \tag{2.18}$$

This equation, together with (2.14) constitutes a system for $\bar{\lambda}$ and $\vec{c} = [c_{li}, c_{ri}]$.

The system given in (2.18) depends on $\psi(\chi_{ri})$ and $\psi(\chi_{li})$. Solving (2.14) ex-

plicitly, we get

$$\psi(x) = \begin{cases} \psi_{l1} \cosh(\theta_- x), & \text{for } 0 < x < \chi_{l1} \\ \psi_{li} \cosh(\theta_+(x - \chi_{li})) + B_{li} \sinh(\theta_+(x - \chi_{li})), & \text{for } \chi_{li} < x < \chi_{ri} \\ \psi_{ri} \cosh(\theta_-(x - \chi_{ri})) + B_{di} \sinh(\theta_-(x - \chi_{ri})), & \text{for } \chi_{ri} < x < \chi_{l(i+1)} \\ \psi_{lK} \cosh(\theta_-(x - 1)), & \text{for } \chi_{rK} < x < 1 \end{cases} \quad (2.19)$$

for $i = 2, \dots, K-1$, where $\psi_{li} \equiv \psi(\chi_{li})$, $\psi_{ri} \equiv \psi(\chi_{ri})$, and B_{li}, B_{di} have yet to be found. We have that $\chi_{ri} - \chi_{li} = l$; similarly, if we define $d \equiv \chi_{l(i+1)} - \chi_{ri} = \frac{1}{K} - l$, and the constants

$$\begin{aligned} c_l &= \cosh(\theta_+ l), & s_l &= \sinh(\theta_+ l), \\ c_d &= \cosh(\theta_- d), & s_d &= \sinh(\theta_- d) \end{aligned}$$

we have that $\psi_{ri} = \psi_{li} c_l + B_{li} s_l$, and that $\psi_{l(i+1)} = \psi_{ri} + B_{di} s_d$. This yields the following conditions

$$\begin{aligned} B_{li} &= \frac{\psi_{ri} - \psi_{li} c_l}{s_l}, \\ B_{di} &= \frac{\psi_{l(i+1)} - \psi_{ri} c_d}{s_d}. \end{aligned}$$

Additionally, the jump condition that solution (2.19) has to satisfy is given by

$$\begin{aligned} -[\psi_x(\chi_{li}^+) - \psi_x(\chi_{li}^-)] &= \frac{\varepsilon^2 \mathcal{V} w_+^2}{\mathcal{D}} c_{li} \equiv b_{li}, \\ -[\psi_x(\chi_{ri}^+) - \psi_x(\chi_{ri}^-)] &= \frac{\varepsilon^2 \mathcal{V} w_+^2}{\mathcal{D}} c_{ri} \equiv b_{ri}, \end{aligned} \quad (2.20)$$

for $i = 1, \dots, K$. We then calculate ψ_x from (2.19) to get

$$\begin{aligned} \psi_x(\chi_{li}^+) &= B_{li} \theta_+, \\ \psi_x(\chi_{li}^-) &= \psi_{r(i-1)} \theta_- s_d + B_{d(i-1)} \theta_- c_d, \\ \psi_x(\chi_{ri}^+) &= B_{di} \theta_-, \\ \psi_x(\chi_{ri}^-) &= u_{li} \theta_+ s_l + B_{li} \theta_+ c_l. \end{aligned}$$

Substituting them into the jump condition yields

$$\begin{aligned}
b_{li} &= \psi_x(\chi_{li}^-) - \psi_x(\chi_{li}^+) = \psi_{r(i-1)}\theta_- s_d + B_{d(i-1)}\theta_- c_d - B_{li}\theta_+ \\
&= \psi_{r(i-1)}\theta_- s_d + \left(\frac{\psi_{li} - \psi_{r(i-1)}c_d}{s_d}\right)\theta_- c_d - \left(\frac{\psi_{ri} - \psi_{li}c_l}{s_l}\right)\theta_+ \\
&= \psi_{r(i-1)}\theta_- \left(s_d - \frac{c_d^2}{s_d}\right) - \psi_{ri}\frac{\theta_+}{s_l} + \psi_{li}\left(\theta_- \frac{c_d}{s_d} + \theta_+ \frac{c_l}{s_l}\right) \\
&= -\psi_{r(i-1)}\frac{\theta_-}{s_d} - \psi_{ri}\frac{\theta_+}{s_l} + \psi_{li}\left(\theta_- \frac{c_d}{s_d} + \theta_+ \frac{c_l}{s_l}\right),
\end{aligned}$$

and similarly,

$$\begin{aligned}
b_{ri} &= \psi_x(\chi_{ri}^-) - \psi_x(\chi_{ri}^+) = \psi_{li}\theta_+ s_l + B_{li}\theta_+ c_d - B_{di}\theta_- \\
&= -\psi_{l(i+1)}\frac{\theta_-}{s_d} - \psi_{li}\frac{\theta_+}{s_l} + \psi_{ri}\left(\theta_+ \frac{c_l}{s_l} + \theta_- \frac{c_d}{s_d}\right),
\end{aligned}$$

for $i = 2, \dots, K-1$. The values at the boundaries are slightly different and have to be derived separately,

$$\begin{aligned}
b_{l1} &= \psi_x(\chi_{l1}^-) - \psi_x(\chi_{l1}^+) = A_0\theta_- \sinh(\theta_- d/2) - B_{l1}\theta_+, \\
b_{rK} &= \psi_x(\chi_{rK}^-) - \psi_x(\chi_{rK}^+) = A_K\theta_- \sinh(\theta_- d/2) + \psi_{lK}\theta_+ s_l + B_{lK}\theta_+ c_l.
\end{aligned}$$

Matching ψ across $x = \chi_{l1}$ and χ_{rK} yields that $A_0 = \frac{\psi_{l1}}{\cosh(\theta_- d/2)}$, and similarly $A_K = \frac{\psi_{rK}}{\cosh(\theta_- d/2)}$. Using the identity

$$\frac{\sinh(x/2)}{\cosh(x/2)} = \frac{\cosh(x) - 1}{\sinh(x)},$$

we finally have that

$$\begin{aligned}
b_{l1} &= \psi_{l1}\left(\theta_- \frac{c_d}{s_d} - \frac{\theta_-}{s_d} + \theta_+ \frac{c_l}{s_l}\right) - \psi_{r1}\frac{\theta_+}{s_l} \\
b_{rK} &= \psi_{rK}\left(\theta_- \frac{c_d}{s_d} - \frac{\theta_-}{s_d} + \theta_+ \frac{c_l}{s_l}\right) - \psi_{lK}\frac{\theta_+}{s_l}.
\end{aligned}$$

We can now write the $2K \times 2K$ system of equations in matrix form as $M\vec{\psi} = \vec{b}$, with M the tridiagonal matrix

$$M = \begin{bmatrix} a+c & b & & & & \\ & b & c & a & & \\ & & a & c & b & \\ & & & \ddots & & \\ & & & & b & c & a \\ & & & & & a & c & b \\ & & & & & & b & c+a \end{bmatrix},$$

and where

$$a = -\frac{\theta_-}{s_d}, \quad b = -\frac{\theta_+}{s_l}, \quad c = \frac{c_d}{s_d}\theta_- + \frac{c_l}{s_l}\theta_+.$$

The eigenpairs of M can be found explicitly (see appendix B in [4]), and for the reader's convenience we will reproduce the calculation. (Probably put it in it's own appendix)

The M matrix can be simplified into $M = Q + cI$, with

$$Q = \begin{bmatrix} a & b & & & & \\ b & 0 & a & & & \\ & a & 0 & b & & \\ & & & \ddots & & \\ & & & & b & 0 & a \\ & & & & & a & 0 & b \\ & & & & & & b & a \end{bmatrix}.$$

We use the property that $\text{eig}(M) = c + \text{eig}(Q)$. We start by looking for an eigenvector $\vec{q} = [z, tz^2, z^3, tz^4, \dots, tz^{2K}]^T$, with $t, z \in \mathbb{C}$, $|z| = 1$, and corresponding eigenvalue σ . From the second equation to the second to last we get the following

system,

$$\begin{aligned} atz^{1-l} + btz^{1+l} &= \sigma z^l, & \text{if } l \text{ is odd,} \\ bz^{1-l} + az^{1+l} &= \sigma t z^l, & \text{if } l \text{ is even.} \end{aligned} \quad (2.21)$$

Since $z\bar{z} = 1$, hence $1/z = \bar{z}$, we can solve for t in the above system to get

$$t = \pm \frac{az + b\bar{z}}{|az + b\bar{z}|},$$

which implies that $|t| = 1$.

In order to satisfy the first and last equations, we look at the extended system $Q(Ah + B\bar{h}) = \sigma(Ah + B\bar{h})$, with $h = [t, \bar{q}, tz^{2K+1}]^T$. The first and last equations are

$$\begin{aligned} a(At + B\bar{t}) + b(Az + B\bar{z}) &= \sigma(At + B\bar{t}), \\ b(Atz^{2K} + B\bar{t}\bar{z}^{2K}) + a(Az^{2K+1} + B\bar{z}^{2K+1}) &= \sigma(Az^{2K+1} + B\bar{z}^{2K+1}). \end{aligned}$$

The first and last equations will then be satisfied if

$$\begin{aligned} At + B\bar{t} &= Az + B\bar{z}, \\ Atz^{2K} + B\bar{t}\bar{z}^{2K} &= Az^{2K+1} + B\bar{z}^{2K+1}. \end{aligned}$$

Nontrivial solutions for A and B exist if

$$(z - t)(1 - \bar{t}\bar{z})\bar{z}^{2K} = (\bar{z} - \bar{t})(1 - tz)z^{2K}$$

is satisfied. Since $|z| = |t| = 1$, we have then that $z^{4K} = 1$. If we write z in polar form, we have that the roots of $z^{4K} = 1$ are $z = e^{i\frac{2\pi(j-1)}{2K}}$, with $j = 1, 2, \dots, 2K$. Substituting it into (2.21), we get

$$\sigma = \pm |az + b\bar{z}| = \pm \sqrt{a^2 + b^2 + 2ab \cos(\theta)},$$

with $\theta = \frac{2\pi(j-1)}{2K}$. Since we have both positive and negative values, we are counting twice when ranging $j = 1, \dots, 2K$; therefore the range can be restricted to obtain the following set of distinct eigenvalues

$$\sigma_{j\pm} = \pm \sqrt{a^2 + b^2 + 2ab \cos \theta_j}, \quad \text{with } \theta_j = \frac{\pi j}{K}, \quad j = 1, \dots, K-1,$$

$$\sigma_{K\pm} = a \pm b.$$

Going back to (2.20), we can express the jump condition as the following system,

$$\vec{\psi} = M^{-1} \vec{b} = \frac{\varepsilon^2 \mathcal{V} w_{\pm}^2}{D} M^{-1} \vec{c},$$

and we can use it to substitute $\vec{\psi}$ in (2.18), resulting in the system

$$\bar{\lambda} \beta \vec{c} = \varepsilon^2 \left(\frac{(L-l)w_{\pm}^2}{4\mathcal{D}} I - \frac{\mathcal{V} w_{\pm}^4}{2\mathcal{D}} M^{-1} \right) \vec{c}. \quad (2.22)$$

Since $\bar{\lambda} = \lambda + \varepsilon^2 m^2$, and $M^{-1} \vec{c} = \hat{\sigma}^{-1} \vec{c}$, with $\hat{\sigma} = c + \sigma$, we have then that in the limit when $\varepsilon \rightarrow 0$,

$$\lim_{\varepsilon \rightarrow 0} \frac{\lambda_{j\pm}}{\varepsilon^2} = -m^2 + \frac{(L-l)w_{\pm}^2}{4\mathcal{D}\beta} - \frac{\mathcal{V} w_{\pm}^4}{2\mathcal{D}\beta} \hat{\sigma}_{j\pm}^{-1}, \quad j = 1, \dots, K.$$

To establish the stability of the system, we want to establish conditions that guarantee that the eigenvalues will be negative, hence stable.

The largest eigenvalue corresponds to the largest $\hat{\sigma}$ value; since both a and b are negative, the largest σ values corresponds to $j = 1$; and as the number of mesas increases the largest eigenvalue tends to $c + |a + b|$.

On the other end of the spectrum, we have that the smallest eigenvalue is always

positive,

$$c + a + b = c - |a + b| = \frac{c_d \theta_-}{s_d} + \frac{c_l \theta_+}{s_l} - \frac{\theta_-}{s_d} - \frac{\theta_+}{s_l} = \frac{s_l \theta_- (c_d - 1) + s_d \theta_+ (c_l - 1)}{s_d s_l},$$

since $\cosh(x) > 1$ for $x \neq 0$.

From (2.15) we have that to leading order both θ_- , $\theta_+ \sim m$. Let

$$\hat{a} = \frac{-1}{\sinh(md)}, \quad \hat{b} = \frac{-1}{\sinh(ml)}, \quad \hat{c} = \coth(md) + \coth(ml),$$

the stability condition is, then

$$\begin{aligned} \frac{(L-l)w_+^2}{4\mathcal{D}\beta} &< m^2 + \frac{\mathcal{V}w_+^4}{2\mathcal{D}\beta} \hat{\sigma}_{j\pm}^{-1} \\ &= m^2 + \frac{Lw_+^2}{2\mathcal{D}\beta lm} \left[\frac{1}{\hat{c} \pm \sqrt{\hat{a}^2 + \hat{b}^2 + 2\hat{a}\hat{b} \cos\left(\frac{\pi j}{K}\right)}} \right], \end{aligned}$$

for all $j = 1, \dots, K-1$, and $m = \frac{k\pi}{d_0}$, $k = 1, \dots$

A sufficient condition for stability is, then, that if

$$\mathcal{D} > \frac{(L-l)w_+^2 d_0^2}{4\pi^2 \beta}$$

then the K -stripe system will be stable.

For the $m = 0$ mode, and to first order, we approximate a , b , and c as

$$a = -\frac{1}{d} + O(\varepsilon), \quad b = -\frac{1}{l} + O(\varepsilon), \quad c = \frac{1}{d} + \frac{1}{l} + O(\varepsilon),$$

Since $\hat{\sigma}_{K+} = a + b + c$ would be zero to first order, we can approximate c to

second order for that particular case, resulting in

$$c = \frac{1}{d} + \frac{1}{l} + \frac{1}{2}(d\theta_-^2 + l\theta_+^2) + O(\epsilon^2).$$

We have then that

$$\begin{aligned}\hat{\sigma}_{j\pm} &\sim \frac{1}{d} + \frac{1}{l} \pm \sqrt{\frac{1}{d^2} + \frac{1}{l^2} + \frac{2}{dl}\cos(\theta_j)}, \quad j = 1, \dots, K-1, \\ \hat{\sigma}_{K+} &\sim \frac{1}{2}(d\theta_-^2 + l\theta_+^2), \\ \hat{\sigma}_{K-} &\sim \frac{2}{l}.\end{aligned}$$

Similarly, we have that the eigenvalues $\lambda_{j\pm}$ for the full system, for the $m = 0$ mode, are

$$\lambda_{K+} = \epsilon^2 \left(\frac{(L-l)w_+^2}{4\mathcal{D}\beta} - \frac{Lw_+^2}{2\mathcal{D}\beta l} \sigma_{K+}^{-1} \right), \quad (2.23a)$$

$$= -\epsilon \frac{Lw_+^2}{\beta l} \left[\frac{1}{K} - \frac{2w_+}{2-w_+} \right]^{-1} + O(\epsilon^2) < 0,$$

$$\lambda_{K-} = \epsilon^2 \left(\frac{(L-l)w_+^2}{4\mathcal{D}\beta} - \frac{Lw_+^2}{2\mathcal{D}\beta l} \frac{l}{2} \right) = -\epsilon^2 \frac{lw_+^2}{4\mathcal{D}\beta} < 0, \quad (2.23b)$$

$$\lambda_{j\pm} = \epsilon^2 \left(\frac{(L-l)w_+^2}{4\mathcal{D}\beta} - \frac{Lw_+^2}{2\mathcal{D}\beta l} \sigma_{j\pm}^{-1} \right), \quad j = 1, \dots, K-1, \quad (2.23c)$$

$$\begin{aligned}&< \epsilon^2 \left(\frac{(L-l)w_+^2}{4\mathcal{D}\beta} - \frac{Lw_+^2}{2\mathcal{D}\beta l} \left[\frac{2}{d} + \frac{2}{l} \right]^{-1} \right), \\ &= \epsilon^2 \left(\frac{(L-l)w_+^2}{4\mathcal{D}\beta} - \frac{Lw_+^2}{2\mathcal{D}\beta l} \left[\frac{l(L-l)}{2L} \right] \right) = 0,\end{aligned}$$

with (2.23a) being negative resulting from the previous numerical estimation $w_+ \sim 3.30$ in (2.5).

This shows that for the mode $m = 0$, all the eigenvalues λ_j , $j = 1, \dots, K$ are negative. Hence, a 1-D K -stripe mesa pattern with $D = O(\epsilon^{-1})$ is a stable solution

to the GMS system.

2.2 Case Study: the generic mesa model

We will study a class of reaction-diffusion equations, that under some conditions exhibit mesa-type solutions. We will construct a general multi-mesa solution, and study its stability.

The system we will study is the following system of reaction diffusion equations:

$$\begin{aligned} u_t &= \varepsilon^2 \Delta u + f(u, v) \\ \tau v_t &= \frac{\mathcal{D}}{\varepsilon} \Delta v + g(u, v), \end{aligned} \tag{2.24}$$

with homogeneous Neumann boundary conditions on $x \in [0, 1] \times [0, d_0]$. We consider the limit where $\varepsilon \ll 1$, and regard all the other constants as being $O(1)$.

2.2.1 Construction of the solution in the near-shadow limit

(Reference to McKay and Kolokolnikov)

We want to construct a K -stripe stationary mesa solution on $x \in [0, 1]$. A mesa structure is characterized as a function $u(x) \sim u_+$ on $-l < x < l$, and $u(x) \sim u_-$ on $l < |x| < L$; with $u_+ > u_-$, and both values joined by a sharp interface.

The mesa pattern will be formed by two back-to-back interfaces. We will start by constructing a solution on $[0, L]$, with the interface centred at $x = l$. A full mesa solution can then be constructed by adding an even reflection (see figure 2.1), and a K -mesa solution will simply be K copies, or $2K$ interfaces. The stationary equation we want to solve is

$$\begin{aligned} 0 &= \varepsilon^2 u_{xx} + f(u, v), & u_x(-L) &= u_x(L) = 0, \\ 0 &= \frac{\mathcal{D}}{\varepsilon} v_{xx} + g(u, v), & v_x(-L) &= v_x(L) = 0. \end{aligned} \tag{2.25}$$

To first order, we have $v_{xx} = 0$. Applying the Neumann boundary condition, we have then that $v \sim \mathcal{V}$, and the value of the constant can be estimated by integrating over the whole domain. The resulting equation is

$$0 = \int_0^L g(u, \mathcal{V}) dx, \quad (2.26)$$

with $v = \mathcal{V}$ constant.

Now, we are looking for a heteroclinic connection in u as the transition mechanism connecting $u = u_+$ to $u = u_-$. This imposes the algebraic constraint that $f(u_+, V) \equiv f_+ = 0$, and $f(u_-, V) \equiv f_- = 0$, which has to be satisfied together with the Maxwell line condition [3] $\int_{u_-}^{u_+} f(w, \mathcal{V}) dw = 0$. For both branches to be stable we also require $f_u(u_{\pm}, \mathcal{V}) < 0$. Solving the algebraic system determines u_{\pm} , and $v_0 = \mathcal{V}$.

In the inner region near the interface of the mesa, we have that $v \sim \mathcal{V}$, and we do a change of variables for $y = \varepsilon^{-1}(x - l)$, and $u(x) \sim U_0(\frac{x-l}{\varepsilon})$. Integrating (2.26) in two parts across the interface yields the following result

$$\begin{aligned} 0 = \frac{D}{\varepsilon} \int_0^l v_{xx} + \int_0^l g(u, \mathcal{V}) dx &\Rightarrow \frac{D}{\varepsilon} v_x(l^-) = -l g_+, \\ 0 = \frac{D}{\varepsilon} \int_l^L v_{xx} + \int_l^L g(u, \mathcal{V}) dx &\Rightarrow \frac{D}{\varepsilon} v_x(l^+) = (L-l) g_-. \end{aligned}$$

Since the v solution doesn't have sharp interfaces, we have then that to first order

$$l = \frac{g_-}{g_- - g_+} L + O(\varepsilon). \quad (2.27)$$

Furthermore, since $0 < l < L$, we have the consistency condition

$$0 < \frac{g_-}{g_- - g_+} < 1,$$

and as with f_{\pm} , we have that $g_{\pm} \equiv g(u_{\pm}, \mathcal{V})$.

We will divide the half-mesa branch into three regions: the outer part on the mesa plateau, $0 < x < l$; the outer part of the mesa beyond the plateau, $x > l$; and the internal layer around $x = l$ bridging the two outer regions.

To zoom into the inner layer we let $y = \frac{x-l}{\varepsilon}$, $u(\varepsilon y + l) \equiv U(y)$, $v(\varepsilon y + l) \equiv V(y)$; which when substituted into (2.25) results in

$$\begin{aligned} U_{yy} + f(U, V) &= 0, & -\infty < y < \infty, & \quad U \rightarrow U_{\pm} \text{ as } y \rightarrow \mp\infty, \\ V_{yy} + \frac{\varepsilon^3}{\mathcal{D}} g(U, V) &= 0, & -\infty < y < \infty, & \quad V \rightarrow V_{\pm} \text{ as } y \rightarrow \mp\infty. \end{aligned} \quad (2.28)$$

In the outer region, $0 < x < l$, we have

$$\begin{aligned} f(u, v) &= 0, & u_x(0) &= 0, \\ v_{xx} + \frac{\varepsilon}{\mathcal{D}} g(u, v) &= 0, & v_x(0) &= 0. \end{aligned}$$

with the boundary conditions stemming from the even symmetry imposed on the mesas. Similarly, for the region $x > l$ we have

$$\begin{aligned} f(u, v) &= 0, & u_x(L) &= 0, \\ v_{xx} + \frac{\varepsilon}{\mathcal{D}} g(u, v) &= 0, & v_x(L) &= 0. \end{aligned} \quad (2.29)$$

Performing an asymptotic expansion $u = u_- + \frac{\varepsilon}{\mathcal{D}} u_1 + \dots$, $v = \mathcal{V} + \frac{\varepsilon}{\mathcal{D}} v_1 + \dots$, and substituting into a Taylor expansion of $f(u, v)$ in (2.29), we obtain

$$f(u_-, \mathcal{V}) + \frac{\varepsilon}{\mathcal{D}} (f_u^- u_1 + f_v^- v_1) + \dots = 0,$$

thus $u_1 = -\frac{f_v^-}{f_u^-} v_1$, where $f_v^{\pm} = f_v(u_{\pm}, \mathcal{V})$, and $f_u^{\pm} = f_u(u_{\pm}, \mathcal{V})$.

From (2.29) we also obtain that

$$\begin{aligned} v_{1xx} &= -g_-, & \text{on } l < x < L, & \quad \text{with } g_- = g(u_-, \mathcal{V}), \\ v_{1x}(L) &= 0, & v_1(l^+) &= v_{1-}, \end{aligned} \quad (2.30)$$

where we have imposed the boundary condition $v_1(l^+) = v_{1-}$ in terms of an unknown constant v_{1-} to be calculated later.

The solution in this region is

$$v_1(x) = -g_- \left(\frac{1}{2}(x-L)^2 - \frac{1}{2}(L-l)^2 \right) + v_{1-}, \quad (2.31)$$

therefore we have that in the outer region $l < x < L$

$$\begin{aligned} u &\sim u_- + \frac{\varepsilon}{\mathcal{D}} \left(-\frac{f_v^-}{g_u^-} v_1(x) \right), \\ v &\sim \mathcal{V} + \frac{\varepsilon}{\mathcal{D}} v_1(x). \end{aligned} \quad (2.32)$$

Either by derivating (2.32), or integrating (2.30) over $l < x < L$ we get that $v_{1x}(l^+) \equiv v'_{1-} = g_-(L-l)$.

An analogous calculation on the outer region $0 < x < l$ yields

$$\begin{aligned} u &\sim u_+ + \frac{\varepsilon}{\mathcal{D}} \left(-\frac{f_v^+}{g_u^+} v_1(x) \right), \\ v &\sim \mathcal{V} + \frac{\varepsilon}{\mathcal{D}} v_1(x), \quad \text{with } v_1(x) = -g_+ \left(\frac{1}{2}x^2 - \frac{l^2}{2} \right) + v_{1+}, \end{aligned}$$

again with a boundary condition $v_1(l^-) = v_{1+}$ in terms of an unknown constant to be found.

$$\begin{aligned} v_{1x}(l^-) &\equiv v'_{1+} = -g_+l, \\ v_{1x}(l^+) &\equiv v'_{1-} = g_-(L-l). \end{aligned} \quad (2.33)$$

Taylor expanding both solutions near $x = l^\pm$ provides matching conditions for the inner solution. The problem for the inner layer, in terms of the variable $y = \varepsilon^{-1}(x - l)$, is

$$\begin{aligned} U_{yy} + f(U, V) &= 0, \quad -\infty < y < \infty, \quad U \sim u_\pm - \frac{\varepsilon}{\mathcal{D}} \frac{f_v^\pm}{f_u^\pm} v_{1\pm} \text{ as } y \rightarrow \mp\infty, \\ V_{yy} &= -\frac{\varepsilon^3}{\mathcal{D}} g(U, V), \quad -\infty < y < \infty, \quad V \sim \mathcal{V} + \frac{\varepsilon}{\mathcal{D}} (V_{1\pm} + \varepsilon y V'_{1\pm}) \text{ as } y \rightarrow \mp\infty. \end{aligned}$$

Expanding the inner solution, $U = U_0 + \frac{\varepsilon}{\mathcal{D}} U_1 + \dots$, $V = V_0 + \frac{\varepsilon}{\mathcal{D}} V_1 + \dots$, we get

$$\begin{aligned} \mathcal{L}(U_1) &= U_{1yy} + f_U(U_0, V_0)U_1 = -f_V(U_0, V_0)V_1, \\ V_{1yy} &= 0. \end{aligned}$$

The matching condition for $V_1 = h_1 y + h_2$ is $V_1 \sim v_{1\pm}$ as $y \rightarrow \mp\infty$. Thus we must have that $h_1 = 0$, and $h_2 = v_{1+} = v_{1-} = V_1$.

We can obtain a solvability condition since by translational invariance we have that $\mathcal{L}(U'_0) = 0$. Hence

$$\int_{-\infty}^{\infty} (U'_0 \mathcal{L}U_1 - U_1 \mathcal{L}U'_0) dy = -V_1 \int_{-\infty}^{\infty} U'_0 f_V(U_0, V_0) dy = 0.$$

We can conclude then that if $f_V \neq 0$ then $V_1 = 0$, thus $V_{1\pm} = 0$. We also have then that $U_1 = cU'_0$, and without loss of generality we take $c = 0$.

To $O(\varepsilon)$ we have then

$$\begin{aligned} v(x) &= \begin{cases} \mathcal{V} + \frac{\varepsilon}{2\mathcal{D}} (g_-(x-L)^2 + g_-(L-l)^2), & l < x < L, \\ \mathcal{V} - \frac{\varepsilon}{2\mathcal{D}} g_+(x^2 - l^2), & 0 < x < l. \end{cases} \\ u(x) &= \begin{cases} u_- + O(\frac{\varepsilon^2}{\mathcal{D}}), & l < x < L, \\ u_+ + O(\frac{\varepsilon^2}{\mathcal{D}}), & 0 < x < l. \end{cases} \end{aligned} \tag{2.34}$$

In the inner region we expand to second order, $u = U_0 + \frac{\varepsilon^2}{\mathcal{D}}U_2 + \dots$, $v = \mathcal{V} + \frac{\varepsilon^2}{\mathcal{D}}V_2 + \dots$, and get

$$\begin{aligned}\mathcal{L}(U_2) &= U_{2yy} + f_U(U_0, V_0)U_2 = -f_V(U_0, V_0)V_2, \\ V_{2yy} &= 0,\end{aligned}$$

with the matching condition that $V_2 \sim yv'_{1\pm}$ as $y \rightarrow \mp\infty$, and v_1 the $O(\varepsilon/\mathcal{D})$ term for $v(x)$ in (2.34).

We must have then that $V_2(y) = H_{20} + yH_{21}$, and we can conclude that $H_{21} = V'_{1+} = V'_{1-}$. Using (2.33), we can now recover the result from (2.27):

$$g_-(L-l) = -g_+l \quad \rightarrow \quad l = \frac{g_-}{g_- - g_+}L.$$

The constant H_{20} can be found in terms of H_{21} via a solvability condition, since $\mathcal{L}U'_0 = 0$, and

$$\mathcal{L}U_2 = U_{2yy} + f_U(U_0, V_0)U_2 = -f_V(U_0, V_0)(H_{20} + yH_{21}),$$

We have then that

$$\begin{aligned}\int_{-\infty}^{\infty} (H_{20} + yH_{21})U'_0 f_V(U_0, V_0)dy &= 0, \\ \text{hence } H_{20} &= -V'_{1\pm} \frac{\int_{-\infty}^{\infty} yU'_0 f_V(U_0, V_0)dy}{\int_{-\infty}^{\infty} U'_0 f_V(U_0, V_0)dy}\end{aligned}$$

In the outer expansion, $v(x) = \mathcal{V} + \frac{\varepsilon}{\mathcal{D}}v_1 + \frac{\varepsilon^2}{\mathcal{D}}v_2$, we require then that $v_2(l) = H_{20}$.

2.2.2 Stability of the K-mesa solution to perturbations along the y-axis

We start by considering a one-mesa steady-state solution to the domain $[-L, L] \times [0, d_0]$. We consider small perturbations of the form

$$\begin{aligned} u(x, y) &= u_e(x) + e^{\lambda t} e^{imy} \phi(x), \\ v(x, y) &= v_e(x) + e^{\lambda t} e^{imy} \psi(x), \end{aligned}$$

which yield the eigenvalue problem

$$\begin{aligned} \lambda \phi &= \varepsilon^2 \phi_{xx} - \varepsilon^2 m^2 \phi + f_u(u_e, v_e) \phi + f_v(u_e, v_e) \psi, \\ \tau \lambda \psi &= \frac{\mathcal{D}}{\varepsilon} \psi_{xx} - \frac{\mathcal{D}}{\varepsilon} m^2 \psi + g_u(u_e, v_e) \phi + g_v(u_e, v_e) \psi. \end{aligned} \tag{2.35}$$

We now multiply the ϕ equation in (2.35) by u_x and integrating by parts on $[0, L]$. Given that the equilibrium problem satisfies $\varepsilon^2 u_{xx} + f(u, v) = 0$, we have then that

$$\varepsilon^2 (u_x)_{xx} + f_u u_x + f_v v_x = 0.$$

We define the operator $\mathcal{L}_\varepsilon u$ by

$$\mathcal{L}_\varepsilon u \equiv \varepsilon^2 u_{xx} + f_u u,$$

and we have then that the equilibrium problem satisfies

$$\mathcal{L}_\varepsilon u_x = \varepsilon^2 (u_x)_{xx} + f_u u_x = -f_v v_x,$$

and from (2.35) we have then that

$$\mathcal{L}_\varepsilon \phi + f_v \psi = \bar{\lambda} \phi.$$

Integrating first on $-L < x < 0$, we have

$$\int_{-L}^0 (u_x \mathcal{L}_\varepsilon \phi - \phi \mathcal{L}_\varepsilon u_x) dx = \varepsilon^2 [u_x \phi_x - \phi u_{xx}] \Big|_{-L}^0.$$

The two terms on the left side of the integral each equate to

$$\begin{aligned} \int_{-L}^0 u_x \mathcal{L}_\varepsilon \phi dx &= \bar{\lambda} \int_{-L}^0 u_x \phi dx - \int_{-L}^0 u_x f_v \psi dx \\ \int_{-L}^0 \phi \mathcal{L}_\varepsilon u_x dx &= - \int_{-L}^0 \phi f_v v_x. \end{aligned}$$

Putting it all together leads to

$$\bar{\lambda} \int_{-L}^0 u_x \phi dx - \int_{-L}^0 u_x f_v \psi dx + \int_{-L}^0 \phi f_v v_x = \varepsilon^2 [u_x \phi_x - \phi u_{xx}] \Big|_{-L}^0.$$

We now make use of the following facts: $u_x(-L) = u_x(0) = 0$ from Neumann boundary conditions and even symmetry considerations, respectively. Both $\psi(x)$ and $v_x(x)$ are approximately constant, hence $\psi(x) \cong \psi(-l)$, $v_x(x) \cong v_x(-l)$. Since $u_x(x)$ is localized near the interface, we have that

$$\int_{-L}^0 u_x \phi dx = c_- \int_{-L}^0 u_x^2 dx.$$

This reduces the equation to

$$\begin{aligned} \bar{\lambda} c_- \int_{-L}^0 u_x^2 dx &\cong \psi(-l) \int_{-L}^0 u_x f_v dx - v_x(-l) c_- \int_{-L}^0 f_v u_x dx - \varepsilon^2 [\phi u_{xx}] \Big|_{-L}^0, \\ \bar{\lambda} c_- \int_{-L}^0 u_x^2 dx &\cong [\psi(-l) - v_x(-l) c_-] \int_{-L}^0 u_x f_v dx - \varepsilon^2 [\phi u_{xx}] \Big|_{-L}^0, \end{aligned}$$

We now estimate

$$\begin{aligned}\phi\Big|_{x=-L} &= O(1), & \phi\Big|_{x=0} &= O(1), \text{ as well as} \\ u_{xx}\Big|_{x=-L} &= O(\varepsilon), & u_{xx}\Big|_{x=0} &= O(\varepsilon),\end{aligned}$$

therefore we have that $\varepsilon^2(\phi u_{xx})\Big|_{-L}^0 = O(\varepsilon^3)$.

Changing variables to $y = \varepsilon^{-1}(x + l)$, we have that

$$\int_{-L}^0 u_x f_v dx \sim \int_{-\infty}^{\infty} U'_0(y) f_v dy = \int_{u_-}^{u_+} f_v du,$$

since $u \rightarrow u_{\pm}$ when $y \rightarrow \pm\infty$. Similarly, we can make the same change of variables to have

$$\int_{-L}^0 u_x^2 dx \sim \int_{-L}^0 \frac{1}{\varepsilon^2} (U'_0)^2 dx = \frac{1}{\varepsilon} \int_{-\infty}^{\infty} (U'_0)^2 dy.$$

This yields the simplified equation

$$\bar{\lambda} c_- \int_{-\infty}^{\infty} (U'_0)^2 dy \sim \varepsilon [\psi(-l) - c_- v_x(-l)] \int_{u_-}^{u_+} f_v du + O(\varepsilon^4).$$

We now define

$$\kappa_0 \equiv \frac{\int_{-\infty}^{\infty} (U'_0)^2 dy}{\int_{u_-}^{u_+} f_v du}.$$

The integral in the denominator, $\int_{-\infty}^{\infty} (U'_0)^2 dy$, can be further estimated by integrating the U equation in (2.28)

$$\int_{-\infty}^{\infty} U_{0y}^2(y) dy \sim \int_0^{u_+} U_{0y}^2 \frac{1}{U_{0y}} dU_0 = \int_0^{u_+} \sqrt{2\mathcal{F}(u)} du,$$

with $\mathcal{F}(u) = -\int_0^u f(s) ds$.

then,

$$\bar{\lambda} \kappa_0 c_- \sim \varepsilon [\psi(-l) - v_x(-l) c_-]$$

Repeating the procedure for the $0 < x < L$ region, we get the analogous equation

$$\bar{\lambda} \kappa_0 c_+ \sim \varepsilon [-\psi(l) + v_x(l) c_+],$$

with the sign change from the fact that with a change of variables $y = \varepsilon^{-1}(x - l)$ and the transition layer at $x = l$, in this region we have $u \rightarrow u_{\pm}$ when $y \rightarrow \mp \infty$.

We recall from (2.31) and (2.32) that $v_x(l) \sim \frac{\varepsilon}{\mathcal{D}} g_-(L - l)$, and we also know from (2.27) that $l = \frac{g_- L}{g_- - g_+}$, therefore

$$v_x(l) = - \left(\frac{\varepsilon}{\mathcal{D}} \right) \frac{g_- g_+ L}{g_- - g_+}.$$

Furthermore, since $v(x)$ is an even function, we have that $v_x(-l) = -v_x(l)$.

We can collect both equations into the following linear system

$$\begin{aligned} \varepsilon^{-1} \bar{\lambda} \kappa_0 \begin{pmatrix} c_+ \\ c_- \end{pmatrix} &\cong \begin{pmatrix} -\psi(l) \\ \psi(-l) \end{pmatrix} + v_x(l) \begin{pmatrix} c_+ \\ c_- \end{pmatrix} \\ &\cong \begin{pmatrix} -\psi(l) \\ \psi(-l) \end{pmatrix} - \left(\frac{\varepsilon}{\mathcal{D}} \right) \frac{g_- g_+ L}{g_- - g_+} \begin{pmatrix} c_+ \\ c_- \end{pmatrix} \end{aligned} \quad (2.36)$$

Remark The goal is to find λ ; to establish the conditions under which the system is linearly stable or unstable it is sufficient to determine the sign of λ . To fully solve the system in (2.36) we need to find $\psi(\pm l)$, and this has to be done by finding the

equilibrium solution for the second equation in (2.35):

$$\psi_{xx} - m^2 \psi + \frac{\varepsilon}{\mathcal{D}}(g_u \phi + g_v \psi) = 0. \quad (2.37)$$

Remark At this point we want to consider solutions consisting of K -mesas. The one mesa problem in $-L < x < L$ can be extended to the K -mesa case on $-L < x < (2K-1)L$ by means of Floquet theory. This can be accomplished for the ψ equation by using the following boundary conditions:

$$\psi((2j-1)L) = z^j \psi(-L), \quad \psi'((2j-1)L) = z \psi'(-L), \quad \text{for } j = 1, \dots, K.$$

At the boundary of the whole interval $[-L, (2K-1)L]$, we have $\psi((2K-1)L) = z^K \psi(-L)$. We can get standard periodic boundary conditions then by choosing $z^K = 1$.

Systems with homogeneous Neumann boundary conditions can be extended to periodic boundary conditions by adding an even reflection on one of the boundaries, yielding a system on twice the original domain. By the same token, a system with periodic boundary conditions, with even symmetry, can be folded in half into an equivalent system with Neumann boundary conditions. Applying this idea to the extended K -mesa system implies that we have to consider $2K$ mesas in the periodic case, and thus $z = e^{2\pi i k / 2K}$, $k = 0, \dots, K-1$.

The case for $K = 1$ has to be considered separately, and will be discussed in detail in § 2.2.3.

Since $u(x)$ is approximately constant except at the interfaces, we can approximate the eigenfunction $\phi \sim c_{\pm} u_x$, and similarly $\psi \sim \psi(\pm l)$ when $x \sim \pm l$.

In the flat regions $|x| < l$ and $l < |x| < L$ we have that $f_u \phi + f_v \psi = \lambda \phi$. We

will show later that $\lambda \ll 1$, and this can be used to approximate

$$\begin{aligned}\phi &\sim -\frac{f_v^+}{f_u^+}\psi && \text{for } |x| < l, \\ \phi &\sim -\frac{f_v^-}{f_u^-}\psi && \text{for } l < |x| < L.\end{aligned}$$

Substituting it into (2.37), we end up with the ODE

$$\psi_{xx} - \sigma_{\pm}^2 \psi = 0, \quad (2.38)$$

which is defined everywhere except at the interfaces, and where

$$\begin{aligned}\sigma_{\pm}^2 &= m^2 + \frac{\varepsilon}{\mathcal{D}} \kappa_{\pm} + \frac{\varepsilon \tau \lambda}{\mathcal{D}}, \text{ with} \\ \kappa_+ &\equiv -\left(g_v^+ - \frac{f_v^+}{f_u^+} g_u^+\right) > 0, && \text{when } |x| < l \\ \kappa_- &\equiv -\left(g_v^- - \frac{f_v^-}{f_u^-} g_u^-\right) > 0, && \text{when } l < |x| < L,\end{aligned} \quad (2.39)$$

and as before, we are using the notation $f_v^+ \equiv \frac{\partial f}{\partial v}(u^+, \mathcal{V})$.

Remark We will eventually show that for $m \neq 0$ we have that $\lambda = O(\varepsilon^2)$, and that $\lambda = O(\varepsilon)$ for $m = 0$. It is tempting to disregard the $\tau \lambda \varepsilon$ term in (2.35), however, we will keep this term in order to analyze the case when $\tau \rightarrow \infty$.

Since ψ is smooth, the jump across $x = \pm l$ can be estimated in the sense of distributions through the term $g_u \phi$. We start with the jump across $x = l$, with the standard inner change of variables $y = \varepsilon^{-1}(x - l)$,

$$\begin{aligned}g_u \phi &\sim g_u c_+ u_x \rightarrow c_+ \int_{l^-}^{l^+} g_u u_x dx \sim c_+ \int_{-\infty}^{+\infty} g_{U_0} U_{0y} dy \\ &\sim c_+ \int_{u_+}^{u_-} g_{U_0} dU_0 \sim c_+ (g_- - g_+).\end{aligned} \quad (2.40)$$

Similarly, for the jump across $x = -l$, with $y = \varepsilon^{-1}(x+l)$, we have

$$\begin{aligned} g_u \phi &\sim g_u c_- u_x \rightarrow c_- \int_{-l^+}^{-l^-} g_u u_x dx \sim c_- \int_{-\infty}^{+\infty} g_{U_0} U_{0y} dy \\ &\sim c_- \int_{u_-}^{u_+} g_{U_0} dU_0 \sim c_- (g_+ - g_-). \end{aligned} \quad (2.41)$$

Therefore, we have

$$g_u \phi \sim c_+ (g_- - g_+) \delta(x-l) + c_- (g_+ - g_-) \delta(x+l),$$

effectively taking into account the contributions from both interfaces.

We can now write (2.38) defined on the whole interval $-L < x < L$ as

$$\psi_{xx} - \sigma_{\pm}^2 \psi = \frac{\varepsilon}{\mathcal{D}} (g_- - g_+) [c_+ \delta(x-l) - c_- \delta(x+l)],$$

with the added conditions that the solution has to be continuous across the interfaces at $x = \pm l$; that the jump conditions $\psi_x|_{-l^+} = c_- s$, and $\psi_x|_{l^-} = c_+ s$ are satisfied; and that the Floquet boundary conditions $\psi(L) = z\psi(-L)$, and $\psi'(L) = z\psi'(-L)$ are satisfied as well.

For the jump conditions we have $s = \frac{\varepsilon}{\mathcal{D}} (g_- - g_+)$

A solution to the system with prescribed continuity across the interfaces is

$$\psi(x) = \begin{cases} \psi(-l) \frac{\cosh[\sigma_-(x+L)]}{\cosh[\sigma_-(L-l)]} + A_L \sinh[\sigma_-(x+l)], & -L < x < -l, \\ \psi(-l) \frac{\sinh[\sigma_+(l-x)]}{\cosh(2\sigma_+l)} + \psi(l) \frac{\sinh[\sigma_+(x+l)]}{\sinh(2\sigma_+l)}, & -l < x < l, \\ \psi(l) \frac{\cosh[\sigma_-(L-x)]}{\cosh[\sigma_-(L-l)]} + A_R \sinh[\sigma_-(x-l)], & l < x < L, \end{cases} \quad (2.42)$$

the four unknowns $A_L, A_R, \psi(l), \psi(-l)$ can be determining by enforcing all four boundary and jump conditions.

We start with the Floquet boundary conditions. The four relevant terms are

$$\begin{aligned}\psi(L) &= \frac{\psi(l)}{\cosh[\sigma_-(L-l)]} + A_R \sinh[\sigma_-(L-l)], \\ z\psi(-L) &= \frac{z\psi(-l)}{\cosh[\sigma_-(L-l)]} - zA_L \sinh[\sigma_-(L-l)], \\ \psi'(L) &= A_R \sigma_- \cosh[\sigma_-(L-l)], \\ z\psi'(-L) &= zA_L \sigma_- \cosh[\sigma_-(L-l)].\end{aligned}$$

From the condition on $\psi'(L) = z\psi'(-L)$, it can immediately be seen that $zA_L = A_R$.

From the condition that $\psi(L) = z\psi(-L)$, we get

$$\frac{\psi(l) - z\psi(-l)}{\cosh[\sigma_-(L-l)]} = -2zA_L \sinh[\sigma_-(L-l)],$$

hence

$$\psi(l) - z\psi(-l) = -zA_L \sinh[2\sigma_-(L-l)] \quad (2.43)$$

For the jump conditions, the four relevant terms are

$$\begin{aligned}\psi_x(l^+) &= -\psi(l)\sigma_- \tanh[\sigma_-(L-l)] + A_R \sigma_-, \\ \psi_x(l^-) &= \psi(l)\sigma_+ \coth(2\sigma_+l) - \psi(-l)\sigma_+ \operatorname{csch}(2\sigma_+l), \\ \psi_x(-l^+) &= \psi(l)\sigma_+ \operatorname{csch}(2\sigma_+l) - \psi(-l)\sigma_+ \coth(2\sigma_+l), \\ \psi_x(-l^-) &= -\psi(-l)\sigma_- \tanh[\sigma_-(L-l)] + A_L \sigma_-.\end{aligned}$$

The two jump conditions, $\psi(l^+) - \psi(l^-) = c_+s$ and $\psi(-l^+) - \psi(-l^-) =$

$-c_-s$, yield

$$\begin{aligned}
& -\psi(l)\sigma_- \tanh[\sigma_-(L-l)] + A_R\sigma_- - \\
& \psi(l)\sigma_+ \coth(2\sigma_+l) + \psi(-l)\sigma_+ \operatorname{csch}(2\sigma_+l) = c_+s, \\
& \psi(-l)\sigma_- \tanh[\sigma_-(L-l)] + A_L\sigma_- - \\
& \psi(l)\sigma_+ \operatorname{csch}(2\sigma_+l) + \psi(-l)\sigma_+ \coth(2\sigma_+l) = c_-s
\end{aligned}$$

Simplifying things slightly, and using $A_R = zA_L$, we get

$$\begin{aligned}
& -\psi(l)(\sigma_- \tanh[\sigma_-(L-l)] + \sigma_+ \coth(2\sigma_+l)) + \psi(-l)\sigma_+ \operatorname{csch}(2\sigma_+l) = c_+s - zA_L\sigma_-, \\
& -\psi(l)\sigma_+ \operatorname{csch}(2\sigma_+l) + \psi(-l)(\sigma_- \tanh[\sigma_-(L-l)] + \sigma_+ \coth(2\sigma_+l)) = c_-s - A_L\sigma_-
\end{aligned} \tag{2.44}$$

Putting together (2.44) and (2.43), we can express $\psi(\pm l)$ as the solution to the linear system

$$\begin{aligned}
\begin{pmatrix} d & e \\ e & d \end{pmatrix} \begin{pmatrix} \psi(l) \\ -\psi(-l) \end{pmatrix} &= -s \begin{pmatrix} c_+ \\ c_- \end{pmatrix} + \sigma_- A_L \begin{pmatrix} z \\ 1 \end{pmatrix}, \\
\begin{pmatrix} z \\ 1 \end{pmatrix}^T \begin{pmatrix} \psi(l) \\ -\psi(-l) \end{pmatrix} &= -A_L z \sinh[2\sigma_-(L-l)]
\end{aligned}$$

with

$$\begin{aligned}
d &\equiv \sigma_- \tanh[\sigma_-(L-l)] + \sigma_+ \coth(2\sigma_+l), \\
e &\equiv \sigma_+ \operatorname{csch}(2\sigma_+l).
\end{aligned}$$

Solving for A_L in the second equation, and substituting it into the first one yields

$$G\vec{r} = -s\vec{c} + \vec{b}_0 \left(\frac{-\vec{b}_1^T \vec{r}}{z\chi} \right),$$

with

$$G = \begin{pmatrix} d & e \\ e & d \end{pmatrix}, \quad r = \begin{pmatrix} \psi(l) \\ -\psi(-l) \end{pmatrix}, \quad c = \begin{pmatrix} c_+ \\ c_- \end{pmatrix},$$

$$\vec{b}_0 = \begin{pmatrix} z \\ 1 \end{pmatrix}, \quad \vec{b}_1 = \begin{pmatrix} 1 \\ z \end{pmatrix}, \quad \chi = \frac{\sinh[2\sigma_-(L-l)]}{\sigma_-}.$$

This yields the matrix problem

$$(G+B)\vec{r} = -s\vec{c}, \quad (2.45)$$

where

$$B = \frac{1}{z\chi} \vec{b}_0 \vec{b}_1^T = \frac{1}{z\chi} \begin{pmatrix} z & z^2 \\ 1 & z \end{pmatrix} = \frac{1}{\chi} \begin{pmatrix} 1 & z \\ \bar{z} & 1 \end{pmatrix},$$

since $z\bar{z} = 1$.

Recall that the eigenvalue system that we want to solve, from (2.36), is

$$\varepsilon^{-1} \bar{\lambda} \kappa_0 \begin{pmatrix} c_+ \\ c_- \end{pmatrix} = \begin{pmatrix} -\psi(l) \\ \psi(-l) \end{pmatrix} + v_x(l) \begin{pmatrix} c_+ \\ c_- \end{pmatrix},$$

or, using compact notation

$$\varepsilon^{-1} \bar{\lambda} \kappa_0 \vec{c} = \vec{r} + v_x(l) \vec{c}. \quad (2.46)$$

Solving for \vec{r} in (2.45), and substituting into (2.46) yields

$$\frac{\varepsilon^{-1} \bar{\lambda} \kappa_0}{s} \vec{c} = (G+B)^{-1} \vec{c} + \frac{v_x(l)}{s} \vec{c}. \quad (2.47)$$

Now,

$$\frac{v_x(l)}{s} = -\frac{\varepsilon}{\mathcal{D}} \frac{g_- g_+ L}{g_- - g_+} \frac{\mathcal{D}}{\varepsilon(g_+ - g_-)} = \frac{g_- g_+ L}{(g_+ - g_-)^2}.$$

Since

$$l = \frac{g_-}{g_- - g_+} L \quad \rightarrow \quad \frac{g_+}{g_-} = 1 - \frac{L}{l},$$

we can then calculate

$$\frac{v_x(l)}{s} = \frac{l^2}{L} \left(1 - \frac{L}{l}\right) = \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L. \quad (2.48)$$

Similarly,

$$\frac{\varepsilon^{-1} \bar{\lambda} \kappa_0}{s} = \frac{\varepsilon^{-1} \bar{\lambda} \kappa_0}{\varepsilon(g_+ - g_-)/\mathcal{D}} = -\frac{\mathcal{D}}{\varepsilon^2} \frac{\bar{\lambda} \kappa_0}{g_-} \frac{l}{L}.$$

Substituting into (2.47), with $\bar{\lambda} = \lambda + \varepsilon^2 m^2$, we obtain

$$(G+B)^{-1} \bar{c} + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L \bar{c} - m^2 \varsigma \bar{c} = \frac{\varsigma}{\varepsilon^2} \lambda \bar{c}, \quad (2.49)$$

with $\varsigma = -\frac{\mathcal{D}}{g_-} \kappa_0 \left(\frac{l}{L}\right)$.

The eigenpairs λ and \bar{c} of (2.49) are given in terms of the spectrum of the two-by-two matrix $(G+B)^{-1}$,

$$(G+B)^{-1} \vec{v}_\pm = \omega_\pm \vec{v}_\pm,$$

they are given as

$$\begin{aligned} \bar{c} &= \vec{v}_+, & \text{and} & \quad \lambda_+ = \frac{\varepsilon^2}{\varsigma} \left[\omega_+ + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L - m^2 \varsigma \right], \\ \bar{c} &= \vec{v}_-, & \text{and} & \quad \lambda_- = \frac{\varepsilon^2}{\varsigma} \left[\omega_- + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L - m^2 \varsigma \right]. \end{aligned} \quad (2.50)$$

This will yield two eigenpairs for each value of z . Thus we only need to find the spectrum of $(G+B)^{-1}$, and this can be done by first calculating the eigenpairs of $G+B$, and then taking the reciprocals of the eigenvalues.

Since the matrix

$$G+B = \begin{pmatrix} d & e \\ e & d \end{pmatrix} + \frac{1}{\chi} \begin{pmatrix} 1 & z \\ \bar{z} & 1 \end{pmatrix}$$

is a Hermitian matrix, then all the eigenvalues must be real, and it is possible to find an orthonormal basis.

We let $(G+B)\vec{v} = \sigma\vec{v}$, and we have

$$\det \begin{pmatrix} d + \frac{1}{\chi} - \sigma & e + \frac{z}{\chi} \\ e + \frac{\bar{z}}{\chi} & d + \frac{1}{\chi} - \sigma \end{pmatrix} = 0.$$

Thus

$$\begin{aligned} \left(d + \frac{1}{\chi} - \sigma\right)^2 &= \left(e + \frac{z}{\chi}\right) \left(e + \frac{\bar{z}}{\chi}\right), \\ &= e^2 + \frac{1}{\chi^2} + \frac{e}{\chi}(z + \bar{z}), \end{aligned}$$

and we have used the fact that $z\bar{z} = 1$.

Thus

$$d + \frac{1}{\chi} - \sigma = \pm \left(e^2 + \frac{1}{\chi^2} + \frac{2e}{\chi} \operatorname{Re}(z) \right)^{1/2},$$

and we can conclude that the eigenvalues of $(G+B)^{-1}$, needed in (2.50), are simply

$$\omega_{\pm} = \frac{1}{d + \frac{1}{\chi} \pm \left(e^2 + \frac{1}{\chi^2} + \frac{2e}{\chi} \operatorname{Re}(z) \right)^{1/2}}.$$

Now, in order to calculate the eigenvectors we first notice that

$$d + \frac{1}{\chi} - \sigma = \pm |f|, \quad \text{where } f = e + \frac{z}{\chi}, \quad \text{and } |f| = (f\bar{f})^{1/2}$$

is the length of the complex vector f .

Thus, for ω_+ we have

$$\begin{pmatrix} d + \frac{1}{\chi} - \sigma & e + \frac{\bar{z}}{\chi} \\ e + \frac{z}{\chi} & d + \frac{1}{\chi} - \sigma \end{pmatrix} \vec{v}_+ = \begin{pmatrix} |f| & f \\ \bar{f} & |f| \end{pmatrix} \vec{v}_+ = \vec{0}, \quad \text{thus} \quad \vec{v}_+ = \begin{pmatrix} |f| \\ -\bar{f} \end{pmatrix}.$$

Similarly, for ω_- we have

$$\begin{pmatrix} -|f| & f \\ \bar{f} & -|f| \end{pmatrix} \vec{v}_- = \vec{0}, \quad \text{thus} \quad \vec{v}_- = \begin{pmatrix} |f| \\ \bar{f} \end{pmatrix}.$$

Notice that in a generalized dot product defined as

$$\vec{a} \cdot \vec{b} = \vec{a}^\dagger \vec{b}, \quad \text{where} \quad \vec{a} = \begin{pmatrix} a_1 \\ \vdots \\ a_N \end{pmatrix}, \quad \vec{a}^\dagger = (\bar{a}_1, \dots, \bar{a}_N),$$

then

$$\vec{v}_+ \cdot \vec{v}_- = (|f|, -f) \begin{pmatrix} |f| \\ \bar{f} \end{pmatrix} = 0,$$

therefore \vec{v}_+, \vec{v}_- are orthogonal with respect to this inner product.

Lemma 1 *The spectrum of $(G+B)^{-1} \vec{v}_\pm = \omega_\pm \vec{v}_\pm$ is as follows:*

$$\begin{aligned} \omega_+ &= \frac{1}{d + \frac{1}{\chi} + |f|} & \vec{v}_+ &= \begin{pmatrix} |f| \\ -\bar{f} \end{pmatrix}, \\ \omega_- &= \frac{1}{d + \frac{1}{\chi} - |f|} & \vec{v}_- &= \begin{pmatrix} |f| \\ \bar{f} \end{pmatrix}, \end{aligned} \tag{2.51}$$

where

$$\begin{aligned} f &= e + \frac{z}{\chi}, & e &= \sigma_+ \operatorname{csch}(2\sigma_+ l), \\ \chi &= \frac{\sinh[2\sigma_-(L-l)]}{\sigma_-}, & d &= \sigma_- \tanh[\sigma_-(L-l)] + \sigma_+ \coth(2\sigma_+ l). \end{aligned}$$

Then, we have that

$$|f| = \left(e^2 + \frac{1}{\chi^2} + \frac{2e}{\chi} \operatorname{Re}(z) \right)^{1/2}, \quad z = e^{i\theta}.$$

Lemma 2 *Consider a steady-state solution of K -mesas on an interval of length $2KL$ with Neumann boundary conditions. Then the linearized problem admits $2K$ eigenvalues.*

The eigenvalues are given by

$$\lambda_{\pm j} = \frac{\varepsilon^2}{\varsigma} \left[\omega_{\pm j} + \left(1 - \frac{L}{l} \right) \frac{l^2}{L^2} L - m^2 \varsigma \right] \quad \text{for } j = 1, \dots, K-1,$$

where

$$\omega_{\pm j} = \frac{1}{d + \frac{1}{\chi} \pm \left(e^2 + \frac{1}{\chi^2} + \frac{2e}{\chi} \cos(\pi j/K) \right)^{1/2}}, \quad j = 1, \dots, K-1.$$

Finally, the two remaining eigenvalues are

$$\lambda_{\pm K} = \frac{\varepsilon^2}{\varsigma} \left[\omega_{\pm K} + \left(1 - \frac{L}{l} \right) \frac{l^2}{L^2} L - m^2 \varsigma \right],$$

with

$$\omega_{+K} = \frac{1}{d+e}, \quad \omega_{-K} = \frac{1}{d-e}.$$

These are the eigenvalues that correspond to a K -mesa pattern generated by

gluing together K mesas.

The various quantities are:

$$\begin{aligned} d &= \sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \coth(2\sigma_+ l), \\ e &= \sigma_+ \operatorname{csch}(2\sigma_+ l), \\ \chi &= \sigma_-^{-1} \sinh[2\sigma_- (L-l)], \\ \sigma_\pm^2 &= m^2 - \frac{\varepsilon}{\mathcal{D}} \left(g_v^\pm - \frac{f_v^\pm}{f_u^\pm} g_u^\pm \right) + \frac{\varepsilon \tau \lambda}{\mathcal{D}}. \end{aligned}$$

Now we calculate with a little algebra

$$\begin{aligned} d + e &= \sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \coth(\sigma_+ l), \\ d - e &= \sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \tanh(\sigma_+ l), \\ d + \frac{1}{\chi} &= \sigma_- (\tanh[\sigma_- (L-l)] + \sigma_+ \operatorname{csch}[2\sigma_- (L-l)]) + \sigma_+ \coth(2\sigma_+ l). \end{aligned}$$

In addition,

$$\left(e^2 + \frac{1}{\chi^2} + \frac{2e}{\chi} \cos(2\pi j/K) \right)^{1/2} = \left[\left(e + \frac{1}{\chi} \right)^2 - \frac{4e}{\chi} \sin^2 \left(\frac{\pi j}{2K} \right) \right]^{1/2},$$

and

$$\begin{aligned} e + \frac{1}{\chi} &= \sigma_+ \operatorname{csch}(2\sigma_+ l) + \sigma_- \operatorname{csch}[2\sigma_- (L-l)], \\ \frac{4e}{\chi} &= 4\sigma_+ \sigma_- \operatorname{csch}(2\sigma_+ l) \operatorname{csch}[2\sigma_- (L-l)]. \end{aligned}$$

Thus

$$\omega_{\pm j} = \frac{1}{d + \frac{1}{\chi} \pm \left[\left(e + \frac{1}{\chi} \right)^2 - \frac{4e}{\chi} \sin^2 \left(\frac{\pi j}{2K} \right) \right]^{1/2}}, \quad j = 1, \dots, K-1.$$

Finally,

$$\varsigma = -\frac{\mathcal{D}}{g_-} \kappa_0 \left(\frac{l}{L} \right), \quad \kappa_0 \equiv \frac{\int_{-\infty}^{\infty} (U'_0)^2 dy}{\int_{u_-}^{u_+} f_v du}, \quad \frac{l}{L} = \frac{g_-}{g_- - g_+}$$

2.2.3 The 1-mesa special case

The case of the stability of a one mesa solution with Neumann boundary conditions will now be considered. This has to be done separately as the Floquet theory used in the K -mesa case is for $j = 1, \dots, K-1$, and so does not include the case for $K = 1$.

The analysis is analogous to what was previously done for K -mesas, and we will start at (2.36), which we write as

$$\varepsilon^{-1} \bar{\lambda} \kappa_0 \begin{pmatrix} c_+ \\ c_- \end{pmatrix} = \begin{pmatrix} -\psi(l) \\ \psi(-l) \end{pmatrix} + v_x(l) \begin{pmatrix} c_+ \\ c_- \end{pmatrix} \quad (2.52)$$

with

$$v_x(l) = \left(\frac{\varepsilon}{\mathcal{D}} \right) \frac{g_- - g_+ L}{g_- - g_+},$$

and $\psi(x)$ satisfies

$$\begin{aligned} \psi(x)_{xx} - \sigma^2 \psi &= \frac{c_+ \varepsilon}{\mathcal{D}} (g_+ - g_-) \delta(x - l) - \frac{c_- \varepsilon}{\mathcal{D}} (g_+ - g_-) \delta(x + l), \\ \psi'(-L) &= \psi'(L) = 0. \end{aligned} \quad (2.53)$$

Analogous with (2.42), we obtain that

$$\psi(x) = \begin{cases} \psi(-l) \frac{\cosh[\sigma_-(x+L)]}{\cosh[\sigma_-(L-l)]}, & -L < x < -l, \\ \psi(-l) \frac{\sinh[\sigma_+(l-x)]}{\sinh(2\sigma_+l)} + \psi(l) \frac{\sinh[\sigma_+(x+l)]}{\sinh(2\sigma_+l)}, & -l < x < l, \\ \psi(l) \frac{\cosh[\sigma_-(L-x)]}{\cosh[\sigma_-(L-l)]}, & l < x < L, \end{cases}$$

with $s = \frac{\varepsilon}{\mathcal{D}} (g_+ - g_-)$.

The unknowns $\psi(\pm l)$ are to be found by satisfying the jump conditions $\psi_x \Big|_{-l^-}^{-l^+} = -c_-s$, and $\psi_x \Big|_{l^-}^{l^+} = c_+s$, hence we get

$$\begin{aligned}\psi(l) [\sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \coth(2\sigma_+ l)] - \psi(-l) \sigma_+ \operatorname{csch}(2\sigma_+ l) &= -c_+s, \\ \psi(l) \sigma_+ \operatorname{csch}(2\sigma_+ l) - \psi(-l) [\sigma_+ \coth(2\sigma_+ l) + \sigma_- \tanh[\sigma_- (L-l)]] &= -c_-s.\end{aligned}$$

We can write this as the linear system

$$\begin{pmatrix} d & e \\ e & d \end{pmatrix} \begin{pmatrix} \psi(l) \\ -\psi(-l) \end{pmatrix} = -s \begin{pmatrix} c_+ \\ c_- \end{pmatrix}, \quad G \equiv \begin{pmatrix} d & e \\ e & d \end{pmatrix},$$

where

$$\begin{aligned}d &\equiv \sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \coth(2\sigma_+ l), \\ e &\equiv \sigma_+ \operatorname{csch}(2\sigma_+ l).\end{aligned}$$

Inverting G and substituting into (2.53), we get

$$\frac{\varepsilon^{-1} \bar{\lambda} \kappa_0}{s} \begin{pmatrix} c_+ \\ c_- \end{pmatrix} = \frac{v_x(l)}{s} \begin{pmatrix} c_+ \\ c_- \end{pmatrix} + G^{-1} \begin{pmatrix} c_+ \\ c_- \end{pmatrix},$$

with $v_x(l)/s$ as in (2.48),

$$\frac{v_x(l)}{s} = \frac{\varepsilon}{\mathcal{D}} \frac{g_- g_+ L}{g_+ - g_-} \frac{\mathcal{D}}{\varepsilon (g_+ - g_-)} = \frac{g_- g_+ L}{(g_+ - g_-)^2} = \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L,$$

and similarly,

$$\frac{\varepsilon^{-1} \bar{\lambda} \kappa_0}{s} = \frac{\varepsilon^{-1} \bar{\lambda} \kappa_0}{(\varepsilon / \mathcal{D})(g_+ - g_-)} = -\frac{\mathcal{D}}{\varepsilon^2 g_-} \bar{\lambda} \kappa_0 \left(\frac{l}{L}\right).$$

Putting it all together, we conclude that

$$G^{-1} \begin{pmatrix} c_+ \\ c_- \end{pmatrix} + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L \begin{pmatrix} c_+ \\ c_- \end{pmatrix} = -\frac{\mathcal{D}}{\varepsilon^2 g_-} \bar{\lambda} \kappa_0 \left(\frac{l}{L}\right) \begin{pmatrix} c_+ \\ c_- \end{pmatrix}, \quad (2.54)$$

with

$$G^{-1} = \frac{1}{d^2 - e^2} \begin{pmatrix} d & -e \\ -e & d \end{pmatrix}.$$

Thus, the stability of a single mesa is governed by (2.54).

Remark As a sanity check, we need to show that (2.54) evaluated for the GMS system yields an equivalent equation as the matrix problem in equation (5.15) of [2].

Similarly, we also need to show that the general K –mesa matrix problem given in (2.49) is also equivalent in the GMS case to the previously computed system in (2.22).

We have from (5.15) of [2] that

$$\left[\frac{L}{2} (1 - L) I - \hat{G}^{-1} \right] \hat{c} = \frac{\alpha}{\varepsilon^2} \bar{\lambda} \hat{c}, \quad \text{with } \hat{c} = \begin{pmatrix} c_l \\ c_r \end{pmatrix}, \quad (2.55)$$

where L is the width of the mesa, and the domain has constant length 1; and

$$\hat{G}^{-1} = \frac{1}{d^2 - e^2} \begin{pmatrix} d & e \\ e & d \end{pmatrix}, \quad \alpha \equiv \frac{2\beta L \mathcal{D}}{w_+^2}, \quad \beta = \int_{-\infty}^{\infty} w'^2 dy.$$

Remark Notice that in the formulation for \vec{c} in (2.40) and (2.41), when compared to \hat{c} , we have that $c_l = c_-$, but $c_r = -c_+$.

Rewriting (2.55) in the notation we have been using, we have that $L = 2l$ is the

width of the mesa, and we have

$$[\hat{G}^{-1} - l(1 - 2l)I] \hat{c} = -\frac{\alpha}{\varepsilon^2} \bar{\lambda} \hat{c}, \quad (2.56)$$

with $\alpha = \frac{2\beta(2l)\mathcal{D}}{w_+^2}$.

Now, in our formulation, if we restrict it to the case $L = 1/2$ (domain length 1), we obtain

$$[G^{-1} - l(1 - 2l)I] \vec{c} = -\frac{\mathcal{D}\kappa_0(2l)}{\varepsilon^2 g_-} \bar{\lambda} \vec{c}. \quad (2.57)$$

For the left hand side, we expand (2.56) as

$$\begin{aligned} -\frac{1}{d^2 - e^2} [dc_l + ec_r] + l(1 - 2l)c_l &= \frac{\alpha}{\varepsilon^2} \bar{\lambda} c_l, \\ \frac{1}{d^2 - e^2} [dc_r + ec_l] - l(1 - 2l)c_r &= -\frac{\alpha}{\varepsilon^2} \bar{\lambda} c_r. \end{aligned}$$

Interchanging the rows, we can write this as

$$\frac{1}{d^2 - e^2} \begin{pmatrix} d & -e \\ -e & d \end{pmatrix} \begin{pmatrix} c_r \\ -c_l \end{pmatrix} - l(1 - 2l) \begin{pmatrix} c_r \\ -c_l \end{pmatrix} = -\frac{\alpha}{\varepsilon^2} \bar{\lambda} \begin{pmatrix} c_r \\ -c_l \end{pmatrix},$$

and since $c_r = -c_+$, and $c_l = c_-$, this system is equivalent to (2.57), provided that the right hand sides match, and that the d and e values are consistent.

Thus, we only need to show that

$$\alpha = \frac{4\beta l \mathcal{D}}{w_+^2} = \frac{2l \kappa_0 \mathcal{D}}{g_-},$$

or, more succinctly, that

$$\frac{2\beta}{w_+^2} = \frac{\kappa_0}{g_-},$$

where

$$\beta = \int_{-\infty}^{\infty} w'^2 dy, \quad U_0 = \mathcal{V}w(y), \quad \kappa_0 = \frac{\int_{-\infty}^{\infty} (U_0')^2 dy}{\int_{u_-}^{u_+} f_v du}, \quad g_- = g(u_-, \mathcal{V}).$$

For the GMS model we have that

$$\begin{aligned} g(u, v) &= -v + u^2, \\ f(u, v) &= -u + \frac{u^2}{v(1 + \kappa u^2)}, \quad \text{and } u_- = 0. \end{aligned}$$

When $v = \mathcal{V}$, we integrate

$$\int_{u_-}^{u_+} f_v du = - \int_0^{u_+} \frac{u^2}{\mathcal{V}^2(1 + \kappa u^2)} du$$

Now, we substitute $u = \mathcal{V}w$, $u_+ = \mathcal{V}w_+$, and get

$$\int_{u_-}^{u_+} f_v du = -\mathcal{V} \int_0^{w_+} \frac{w^2}{1 + b_0 w^2} dw, \quad \text{with } b_0 = \kappa \mathcal{V}^2$$

From the definition of the system in (2.4), we have that

$$w'' - w + \frac{w^2}{1 + b_0 w^2} = 0.$$

Multiplying by w' and integrating from $y = -\infty$ to $y = \infty$, we get

$$\begin{aligned} \frac{w'^2}{2} \Big|_{-\infty}^{\infty} - \frac{w^2}{2} \Big|_{-\infty}^{\infty} + \int_{-\infty}^{\infty} \frac{w^2}{1 + b_0 w^2} \frac{dw}{dy} dy &= 0, \\ -\frac{w_+^2}{2} + \int_0^{w_+} \frac{w^2}{1 + b_0 w^2} dw &= 0. \end{aligned}$$

Hence

$$\int_0^{w_+} \frac{w^2}{1+b_0 w^2} dw = \frac{w_+^2}{2},$$

and we can conclude that

$$\int_{u_-}^{u_+} f_v du = -\mathcal{V} \frac{w_+^2}{2}.$$

We also calculate that

$$\int_{-\infty}^{\infty} (U'_0)^2 dy = \mathcal{V}^2 \int_{-\infty}^{\infty} (w')^2 dy, \quad g_- = g(u_-, \mathcal{V}) = -\mathcal{V}.$$

We conclude that

$$\frac{\kappa_0}{g_-} = \frac{\mathcal{V}^2 \int_{-\infty}^{\infty} (w')^2 dy}{-\mathcal{V}(-\mathcal{V} w_+^2/2)} = \frac{2}{w_+^2} \int_{-\infty}^{\infty} (w')^2 dy.$$

Now, the only thing remaining to ensure compatibility between our result and (5.15) of [2] (??? Their formula for θ doesn't include the λ terms???) is to show that the decay rates σ_{\pm} and θ_{\pm} are the same.

We have from (2.39) that

$$\begin{aligned} \sigma_{\pm}^2 &= m^2 + \frac{\varepsilon}{\mathcal{D}} (\kappa_{\pm} + \tau \lambda), \text{ with} \\ \kappa_+ &\equiv - \left(g_v^+ - \frac{f_v^+}{f_u^+} g_u^+ \right) > 0, \\ \kappa_- &\equiv - \left(g_v^- - \frac{f_v^-}{f_u^-} g_u^- \right) > 0, \end{aligned}$$

and from (2.15) that θ_{\pm} is

$$\theta = \begin{cases} \theta_- \equiv \left(m^2 + \frac{\varepsilon(1+\tau\lambda)}{\mathcal{D}} \right)^{1/2}, \\ \theta_+ \equiv \left(m^2 + \frac{\varepsilon(1+\tau\lambda)}{\mathcal{D}} \left(1 + \frac{2w_+}{l(w_+-2)} \right) \right)^{1/2} \end{cases}$$

We have that, for the GMS system,

$$u_- = 0 \quad u_+ = \mathcal{V} w_+, \quad v = \mathcal{V}, \quad \text{where } \mathcal{V} = \frac{1}{w_+^2 2l}.$$

Now, we have that $g_u^- = 0$, and $g_v^- = -1$, hence $\kappa_- = 1$, and thus $\theta_- = \sigma_-$.

Similarly, (??? I've kept the original notation with κ instead of μ , but at one point I guess I'll have to change it???) since u_+ satisfies $f(u_+, \mathcal{V}) = 0$, and thus

$$u_+ = \mathcal{V}(1 + \kappa u_+^2),$$

we have,

$$\begin{aligned} g_u^+ &= 2u_+, \quad f_u^+ = -1 + \frac{2u_+}{\mathcal{V}(1 + \kappa u_+^2)^2} = -1 + \frac{2}{1 + \kappa u_+^2} = -1 + \frac{2\mathcal{V}}{u_+}, \\ g_v^+ &= -1, \quad f_v^+ = -\frac{u_+^2}{\mathcal{V}^2(1 + \kappa u_+^2)} = -\frac{u_+}{\mathcal{V}}. \end{aligned}$$

We have then

$$\begin{aligned} \kappa_+ &= -\left(g_v^+ - \frac{f_v^+}{f_u^+} g_u^+\right) = -\left(-1 + \frac{u_+/\mathcal{V}}{\frac{2\mathcal{V}-u_+}{u_+}} 2u_+\right) = 1 + \frac{2u_+^3}{\mathcal{V}u_+ - 2\mathcal{V}^2} \\ &= 1 + \frac{2\mathcal{V}w_+^3}{w_+ - 2} = 1 + \frac{w_+}{l(w_+ - 2)}. \end{aligned}$$

This shows that $\sigma_{\pm} = \theta_{\pm}$, hence the GMS results in (5.15) of [2] are consistent with ours, and thus constitute a particular case of our results.

Our final result is that on a domain $[-L, L]$, with mesa width $2l$, we have

$$G^{-1} \begin{pmatrix} c_+ \\ c_- \end{pmatrix} + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L \begin{pmatrix} c_+ \\ c_- \end{pmatrix} = -\frac{\mathcal{D}}{\varepsilon^2 g_-} \bar{\lambda} \kappa_0 \left(\frac{l}{L}\right) \begin{pmatrix} c_+ \\ c_- \end{pmatrix}, \quad (2.58)$$

where

$$\begin{aligned}
G^{-1} &= \frac{1}{d^2 - e^2} \begin{pmatrix} d & -e \\ -e & d \end{pmatrix}, \\
d &= \sigma_- \tanh[\sigma_- (L - l)] + \sigma_+ \coth(2\sigma_+ l), \\
e &= \sigma_+ \operatorname{csch}(2\sigma_+ l), \\
\sigma_{\pm}^2 &= m^2 + \frac{\varepsilon}{\mathcal{D}}(\kappa_{\pm} + \tau\lambda), \\
\kappa_+ &= -\left(g_v^+ - \frac{f_v^+}{f_u^+} g_u^+\right) > 0, \\
\kappa_- &= -\left(g_v^- - \frac{f_v^-}{f_u^-} g_u^-\right) > 0, \\
\bar{\lambda} &= \lambda + \varepsilon^2 m^2, \\
g_- &= g(u_-, \mathcal{V}), \\
\kappa_0 &= \frac{\int_{-\infty}^{\infty} (U'_0)^2 dy}{\int_{u_-}^{u_+} f_v du}.
\end{aligned}$$

It is now convenient to define

$$\varsigma = -\frac{\mathcal{D}}{g_-} \kappa_0 \left(\frac{l}{L}\right).$$

Then, with I the identity matrix, we can rewrite (2.58) as

$$\left(G^{-1} + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} LI - m^2 \varsigma I\right) \vec{c} = \frac{\varsigma}{\varepsilon^2} \lambda \vec{c}$$

The eigenpairs of the system are then

$$\begin{aligned}
\lambda_{\pm} &= \frac{\varepsilon^2}{\varsigma} \left[\omega_{\pm} + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L - m^2 \varsigma \right], \\
\vec{c}_{\pm} &= \begin{pmatrix} 1 \\ \mp 1 \end{pmatrix},
\end{aligned} \tag{2.59}$$

with ω_{\pm} the eigenvalues of G^{-1} , given by

$$\begin{aligned}\omega_+ &= \frac{1}{d-e} = [\sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \tanh(l\sigma_+)]^{-1}, \\ \omega_- &= \frac{1}{d+e} = [\sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \coth(l\sigma_+)]^{-1},\end{aligned}$$

The (λ_+, \vec{c}_+) eigenpair corresponds then to the breather mode, and the (λ_-, \vec{c}_-) is the zigzag mode.

- The case $m \neq 0$, $\tau = O(1)$:

We have that irrespective of the sign of ς , for m sufficiently large both, we will have that $\lambda_{\pm} < 0$, i.e., the stripe is stable to short wavelength perturbations in the y -direction.

We have that $\omega_{\pm} > 0$, and in fact as $L \rightarrow \infty$ we have $\omega_{\pm} \sim \frac{1}{2m}$. Given that $1 - L/l < 0$, with the ratio L/l remains constant when only the domain length L is increased, we have that on a small enough domain the stripe will always be stable, and that there will be a critical length L beyond which the stripe will become unstable.

- The case $m = 0$, $\tau = O(1)$:

When $\varepsilon \rightarrow 0$ we have that $\sigma_{\pm} \rightarrow 0$. For the zigzag mode (λ_-) , we have that

$$\sigma_+ \coth(\sigma_+ l) = \frac{\sigma_+}{\tanh(\sigma_+ l)} \sim \frac{1}{l(1 - \frac{\sigma_+^2 l^2}{3})} \sim \frac{1}{l} + O(\sigma_+^2),$$

and since $\sigma_- \tanh[\sigma_- (L-l)] \sim \sigma_-^2 (L-l)$, we have

$$\omega_- \sim \left[\sigma_-^2 (L-l) + \frac{1}{l} + O(\sigma_+^2) \right]^{-1} = l + O(\sigma_+^2, \sigma_-^2).$$

We conclude that for $m = 0$ we have

$$\lambda_- \simeq \frac{\varepsilon^2}{\varsigma} \left[\left(1 - \frac{L}{l} \right) \frac{l^2}{L^2} L + l + O(\sigma_+^2, \sigma_-^2) \right] \sim \frac{\varepsilon^2}{\varsigma} \left[\left(\frac{l^2}{L^2} \right) L + O(\sigma_+^2, \sigma_-^2) \right],$$

and stability is guaranteed for this mode when $\varsigma < 0$

Remark When $\tau \ll 1$ this analysis is consistent provided that the term in $\omega_{\pm} \varepsilon \tau \lambda \ll 1$. Since this shows that $\lambda = O(\varepsilon^2)$, the condition for self-consistency is that $\tau \ll O(\varepsilon^3)$.

Now, for the breather mode λ_+ , we have that

$$\omega_+ \sim \frac{1}{\sigma_-^2(L-l) + \sigma_+^2 l} = \frac{1}{\sigma_-^2 L + l(\sigma_+^2 - \sigma_-^2)}.$$

Since $\sigma_-^2 = \frac{\varepsilon}{\mathcal{D}}(\kappa_- + \tau\lambda)$, and $\sigma_+^2 - \sigma_-^2 = \frac{\varepsilon}{\mathcal{D}}(\kappa_+ - \kappa_-)$, we have that

$$\omega_+^2 \sim \frac{\mathcal{D}}{\varepsilon L [(\kappa_- + \tau\lambda) + \frac{l}{L}(\kappa_+ - \kappa_-)]}.$$

In terms of the breather eigenvalue, this yields that

$$\lambda_+ = \frac{\varepsilon^2}{\varsigma} \left[\omega_+ + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L \right] \sim \frac{\varepsilon \mathcal{D}}{L \varsigma} \frac{1}{(\kappa_- + \tau\lambda) + \frac{l}{L}(\kappa_+ - \kappa_-)}.$$

Notice again that since $l/L < 1$ we have stability of this mode provided that $\varsigma < 0$.

Remark Notice that the breather eigenvalue $\lambda_+ = O(\varepsilon)$, while the zigzag eigenvalue $\lambda_- = O(\varepsilon^2)$.

The consistency condition for the breather case is that $0 < \tau < O(\varepsilon^{-1})$, since $\lambda_+ = O(\varepsilon, \tau\lambda)$.

2.2.4 Hopf bifurcation on 1-d mesa patterns

The eigenvalues of 1-d mesa patterns are given by (2.59), when taking $m = 0$,

$$\begin{aligned}\lambda_+ &= \frac{\varepsilon^2}{\varsigma} \left[\omega_+ + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L \right], \\ \lambda_- &= \frac{\varepsilon^2}{\varsigma} \left[\omega_- + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L \right],\end{aligned}\tag{2.60}$$

where

$$\begin{aligned}\omega_+ &= \frac{1}{d-e} = [\sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \tanh(l\sigma_+)]^{-1}, \\ \omega_- &= \frac{1}{d+e} = [\sigma_- \tanh[\sigma_- (L-l)] + \sigma_+ \coth(l\sigma_+)]^{-1},\end{aligned}$$

with

$$\sigma_{\pm} = \sqrt{\frac{\varepsilon}{\mathcal{D}}(\kappa_{\pm} + \tau\lambda)}, \quad \varsigma = -\frac{\mathcal{D}}{g_-} \kappa_0 \frac{l}{L}.\tag{2.61}$$

Remark There are several distinguished limits in τ that are relevant.

Case I: The natural distinguished limit is when $\lambda_{\pm} = O(\varepsilon^2)$. In this limit we need both ω_+ and ω_- to satisfy $\omega_{\pm} = O(1)$, and thus we require that $\sigma_{\pm} = O(1)$ (we showed earlier that ω_+ and ω_- have different limits as $\sigma_{\pm} \rightarrow 0$).

To satisfy this condition we require that $\frac{\varepsilon\tau\lambda}{\mathcal{D}} = O(1)$ in order to have $\sigma_{\pm} = O(1)$. Given that $\lambda = O(\varepsilon^2)$, this means that $\tau = O(\varepsilon^{-3})$.

The equations can be simplified by eliminating some constants via a suitable change of variables. Let τ_0 and Λ be defined as

$$\lambda = -\frac{\varepsilon^2}{\varsigma} \Lambda, \quad \tau = -\frac{1}{\varepsilon^3} \varsigma \mathcal{D} \tau_0.$$

From (2.61) we obtain

$$\sigma_{\pm} = \sqrt{\tau_0 \Lambda} + O(\varepsilon),$$

and the equations in (2.60) become

$$\begin{aligned}\Lambda &= -\frac{1}{\sqrt{\tau_0 \Lambda} [\tanh(\sqrt{\tau_0 \Lambda}(L-l)) + \tanh(\sqrt{\tau_0 \Lambda}l)]} - \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L, \\ \Lambda &= -\frac{1}{\sqrt{\tau_0 \Lambda} [\tanh(\sqrt{\tau_0 \Lambda}(L-l)) + \coth(\sqrt{\tau_0 \Lambda}l)]} - \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L,\end{aligned}$$

for the zigzag and breather eigenvalues, respectively.

In order to find the Hopf bifurcation values, we let $\Lambda = i\delta/\tau_0$, and for the zigzag case we get

$$F_+ = \frac{i\delta}{\tau_0} + \frac{1}{\sqrt{i\delta} [\tanh(\sqrt{i\delta}(L-l)) + \tanh(\sqrt{i\delta}l)]} + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L = 0.$$

We must now find values for δ and τ such that

$$F_+ = \text{Re}[F_+] + i\text{Im}[F_+] = 0,$$

hence we require both $\text{Re}[F_+] = 0$ and $\text{Im}[F_+] = 0$.

We have then that the Hopf bifurcation values in (2.60) are the roots of

$$\text{Re} \left[\frac{1}{\sqrt{i\delta} [\tanh(\sqrt{i\delta}(L-l)) + \tanh(\sqrt{i\delta}l)]} \right] + \left(1 - \frac{L}{l}\right) \frac{l^2}{L^2} L = 0, \quad (2.62a)$$

$$\text{Im} \left[\frac{1}{\sqrt{i\delta} [\tanh(\sqrt{i\delta}(L-l)) + \tanh(\sqrt{i\delta}l)]} \right] + \frac{\delta}{\tau_0} = 0. \quad (2.62b)$$

This setup decouples the system in terms of finding δ and τ_0 . To find both values one must start by solving (2.62a) in terms of δ , and then substitute the values into (2.62b) in order to find τ_0

$$\tau_0 = - \frac{\delta}{\text{Im} \left[\frac{1}{\sqrt{i\delta} [\tanh(\sqrt{i\delta}(L-l)) + \tanh(\sqrt{i\delta}l)]} \right]}$$

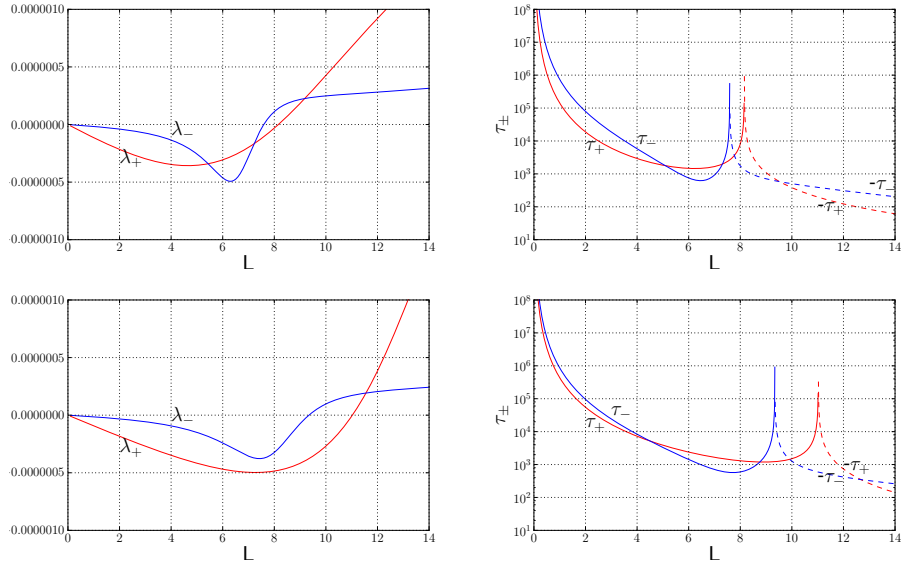

Figure 2.3: Plots of both τ and λ as a function of the domain length L . The parameters used in the computations are $D = 50$, $\varepsilon = 0.01$. The two top figures used $\kappa = 1$, and the bottom figures $\kappa = 0.65$.

Using a straightforward Newton method the system can be easily solved, Figure 2.3 shows the Hopf curves for both λ and τ . At the point where the eigenvalues become positive, the critical value of τ becomes discontinuous, and throughout the range where λ_{\pm} remains negative the breather eigenvalue is always smaller for small values of L , and in some cases the zigzag eigenvalue can become smaller. A similar thing happens with the critical τ values, although their behaviour doesn't

exactly mimic the eigenvalues, as seen in the two bottom images in figure 2.3.

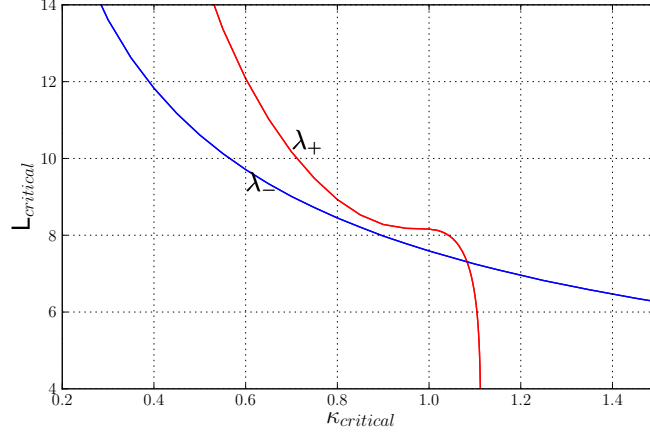

Figure 2.4: The critical values of (κ, L) at which the breather and zigzag eigenvalues change sign.

We will now compute a full time-dependent solution for the case where $\tau = O(\varepsilon^{-3})$, and $\lambda = O(\varepsilon^2)$.

We start again with the full system (2.24),

$$\begin{aligned} u_t &= \varepsilon^2 \Delta u + f(u, v) \\ \tau v_t &= \frac{\mathcal{D}}{\varepsilon} \Delta v + g(u, v), \end{aligned}$$

where we look for a time-dependent mesa solution (???figure) on the domain $[-L, L]$, with the two interfaces located at $x = l_1$ and $x = l_2$. Since $\lambda = O(\varepsilon^2)$, the proper time scale the interfaces is

$$l_1 \equiv l_1(\varepsilon^2 t); \quad l_2 \equiv l_2(\varepsilon^2 t).$$

We also let $\tau = \tilde{\tau}_0/\varepsilon^3$, and we define $T = \varepsilon^2 t$.

We have then that (2.24) becomes

$$\begin{aligned}\varepsilon^2 u_T &= \varepsilon^2 \Delta u + f(u, v) \\ \frac{\tilde{u}_0}{\varepsilon} v_t &= \frac{\mathcal{D}}{\varepsilon} \Delta v + g(u, v).\end{aligned}\tag{2.63}$$

We now do an asymptotic expansion near around the rightmost layer (a similar expansion will also have to be computed for the leftmost layer), with

$$\begin{aligned}u &= U_0(y_1) + \varepsilon U_{1R}(y_1) + \cdots, \\ v &= V_0 + \varepsilon V_{1R} + \varepsilon^2 V_{2R} + \cdots,\end{aligned}$$

where $y = \varepsilon^{-1}(x - l_1(T))$, and therefore $u_T = -\varepsilon^{-1}U'_0 l'_1$. Substituting into (2.63), we obtain that

$$-\varepsilon^{-1}U'_0 l'_1 = U''_0 + \varepsilon U''_{1R} + f(U_0, V_0) + \varepsilon f'_U U_{1R} + \varepsilon f'_V V_{1R} + \cdots$$

As before we take $V_0 = \text{constant}$, and define u_+, u_-, V_0 in terms of the Maxwell heteroclinic line condition

$$\int_{u_-}^{u_+} f(u, V_0) du = 0, \quad f(u_{\pm}, V_0) = 0, \quad f_u(u_{\pm}, V_0) < 0.$$

Thus, around the right transition layer we have

$$U''_{1R} + f'_u U_{1R} = -f'_V V_{1R} - l'_1 U'_0, \quad -\infty < x < \infty.$$

Similarly, for the V equation we have

$$\tilde{V}_0 V_{1T} = \frac{\mathcal{D}}{\varepsilon^3} (V''_0 + \varepsilon V''_1 + \cdots) + g(U_0, V_0) + \cdots$$

Since $V_0 = \text{constant}$ we have that

$$O(1) = \frac{1}{\varepsilon^2} \mathcal{D}V_{1R}'' + O(1),$$

therefore $V_{1R}'' = 0$. We also have that $V \sim V_0$ on the entire interval, therefore in the internal region we cannot have V_{1R} growing at infinity, hence

$$V_{1R} = V_{1R}(T),$$

independent of y .

The inner problem on the rightmost layer is

$$\mathcal{L}U_1 \equiv U_1'' + f_u^0 U_1 = -f_v^0 V_{1R} - l_1' U_0'.$$

Since $\mathcal{L}U_0' = 0$, the solvability condition is

$$-l_1' \int_{-\infty}^{\infty} U_0'^2 dy - V_{1R} \int_{-\infty}^{\infty} f_v^0 U_0' dy = 0,$$

and as we did before, since U_0 is a heteroclinic connection,

$$\int_{-\infty}^{\infty} f_v^0 U_0' dy = \int_{u_+}^{u_-} f_v^0 dU_0 = - \int_{u_-}^{u_+} f_v^0 dU_0.$$

Thus, the ODE for the rightmost layer is

$$l_1' = \frac{dl_1}{dT} = V_{1R}(T) \frac{\int_{u_-}^{u_+} f_v^0 dU_0}{\int_{-\infty}^{\infty} U_0'^2 dy}.$$

The same procedure on the leftmost layer at $x = l_2$ yields that

$$l_2' = -V_{1L}(T) \frac{\int_{u_-}^{u_+} f_v^0 dU_0}{\int_{-\infty}^{\infty} U_0'^2 dy}.$$

To find values for V_{1L} and V_{1R} we need to match with the outer solution
